

Giant cell arteritis occurs at similar rate in blacks, whites

August 9 2019

(HealthDay)—Biopsy-proven giant cell arteritis (BP-GCA) occurs at a

similar rate among white and black patients, according to a study published online Aug. 8 in *JAMA Ophthalmology*.

Anna M. Gruener, B.M.B.S., from the Johns Hopkins Wilmer Eye Institute in Baltimore, and colleagues conducted a retrospective cohort study involving all 586 patients (28.5 percent black; 65.2 percent white) who underwent temporal artery biopsy from July 1, 2007, through Sept. 30, 2017, to examine the incidence of BP-GCA.

The researchers found that within the study population, the crude annual incidence rates for BP-GCA were 2.9 (95 percent confidence interval [CI], 1.3 to 5.5) and 4.2 (95 percent CI, 3.0 to 5.6) per 100,000 for black and white patients, respectively. For black and white patients, the population-adjusted age- and sex-standardized incidence rates were 3.1 (95 percent CI, 1.0 to 5.) and 3.6 (95 percent CI, 2.5 to 4.7), respectively, per 100,000 patients (difference, 0.5; 95 percent CI, -1.7 to 2.7; $P = 0.70$). The incidence rate ratio was significantly elevated for women versus men (1.9; 95 percent CI, 1.1 to 3.4; $P = 0.03$), but was not significant in white versus [black patients](#) (1.2; 95 percent CI, 0.6 to 2.4; $P = 0.66$).

"Whereas previous reports have suggested that GCA is several times more common in white than in black patients, in our study, a difference by race could not be identified," the authors write. "We therefore recommend that the same clinical thresholds for diagnosing and managing GCA be applied to black and [white patients](#)."
