

Common sites of bone erosion in rheumatoid arthritis ID'd on US

October 31 2019

(HealthDay)—Joint recesses with bone erosion are more likely to exhibit

greater severity of joint inflammation on ultrasound (US) examination, according to a study published online Oct. 25 in the *Journal of Clinical Ultrasound*.

York Kiat Tan, from Singapore General Hospital, and colleagues used an extended 36-joint sonographic examination in 30 patients with [rheumatoid arthritis](#) to identify [joints](#) commonly exhibiting [bone erosion](#). A combined US score (CUS) was calculated by summing power Doppler (PD) and gray-scale (GS) joint inflammation scores (semi-quantitative [0 to 3] grading) at each joint recess.

The researchers observed [bone](#) erosion in 144 of 1,080 joints (13.3 percent) and 189 of 1,800 joint recesses (10.5 percent). The wrist (34 percent of 144), first metatarsophalangeal joint (13.2 percent), thumb interphalangeal joint (9 percent), second metacarpophalangeal joint (MCPJ; 7.6 percent), and third MCPJ (7.6 percent) were the joints most frequently associated with bone erosion. With and without bone erosion, mean US scores for joint recesses were a PD of 0.36 versus 0.01; GS of 1.77 versus 0.47; and CUS of 2.13 versus 0.49.

"Our findings extend the current recommendations, which have focused mainly on US of small joints of the hand and feet, and address the gaps in the literature by including more peripheral joint sites in the US assessment," the authors write.
