*Helicobacter pylori* infects approximately half of the world's population and is the strongest known risk factor for developing gastric cancer. Gastric cancer is the third most lethal cancer worldwide.

A cluster of genes called the "cag pathogenicity island" renders some

strains of *H. pylori* particularly virulent. However, it is not clear exactly how *H. pylori* induces gastric cancer.

Now in a study published in the *Proceedings of the National Academy of Sciences*, Lydia Wroblewski, Ph.D., Richard Peek, MD, and collaborators have shown that in chronically infected mice, carcinogenic strains of *H. pylori* mobilize a [transmembrane protein](#) that marks a distinct population of progenitor cells called Lrig1.

*H. pylori* was found to stimulate Lrig1-expressing progenitor cells in a cag-dependent manner, and these reprogrammed cells gave rise to a full spectrum of differentiated cells. Moreover, in human samples, Lrig1 expression was enhanced in gastric lesions with premalignant potential.

These findings provide further insight into the detrimental events that develop in response to *H. pylori* infection.
