

Gilteritinib superior in relapsed, refractory FLT3-mutated AML

October 31 2019

(HealthDay)—For relapsed or refractory acute myeloid leukemia (AML)

with mutations in the FMS-like tyrosine kinase 3 gene (*FLT3*), treatment with a selective FLT3 inhibitor, gilteritinib, results in significantly longer survival and a greater percentage of patients with remission than salvage chemotherapy, according to a study published in the Oct. 31 issue of the *New England Journal of Medicine*.

Alexander E. Perl, M.D., from the Abramson Cancer Center at the University of Pennsylvania in Philadelphia, and colleagues randomly assigned adults with relapsed or refractory *FLT3*-mutated AML to receive either gilteritinib or salvage chemotherapy (247 and 124 patients, respectively) in a phase 3 trial.

The researchers found that [median overall survival](#) was significantly longer in the gilteritinib versus the chemotherapy group (9.3 versus 5.6 months; hazard ratio for death, 0.64; 95 percent confidence interval [CI], 0.49 to 0.83; P

"We found that in this population of patients, gilteritinib resulted in superior overall [survival](#) and percentages of [remission](#) as compared with salvage [chemotherapy](#)," the authors write.

Several authors disclosed financial ties to [pharmaceutical companies](#), including Astellas Pharma, which manufactures gilteritinib and funded the study.
