

# How you experience the menopause may have a lot to do with your family

The [menopause](#) happens around the age of 50, and for many women, the

end of their fertile life is accompanied by uncomfortable symptoms, such as hot flashes, night sweats and anxiety. In the West, it is generally taken as read that these symptoms are a normal part of the menopause. But [cross-cultural research](#) suggests that menopause symptoms are not necessarily inevitable.

For example, [Japanese women](#) rarely report hot flashes, whereas for European women they are a common complaint. As a result, scientists have begun to focus on what causes this difference in experience and the potential impact that behavioural and [lifestyle factors](#), such as [smoking](#), might have.

Our latest [study](#) adds to this knowledge. We found that living away from your genetic [family](#) may worsen the menopause.

## Family matters?

Where people live once they're married varies across cultures. To investigate whether these different living arrangements affect menopause symptoms, we travelled to south-west China to collect data.

In this region, there are groups with distinct living arrangements. First, the Han and the Yi, in which women typically leave their family after they've got married and live with their husband's family. Second, the Mosuo and Zhaba, who engage in the practice of *zou hun* ("[walking marriage](#)"), where the husband and wife live separately with their own related families, and only visit each other at night.

We found that women who remained living with their own family following marriage had significantly less severe menopause symptoms than those who went to live with their husband's family.

## In-law conflict

Many anthropologists are interested in how different levels of relatedness within households can have behavioural and physiological implications. For the menopause, we think the difference in [symptom](#) severity between the groups may be the result of the different levels of conflict that result from being more or less related to other members of your household.

If a woman lives with her husband's family, then until she has children, she is unrelated to anyone in the household. This lack of relatedness can cause [tension](#) between the new wife and her husband's relatives as they have little direct genetic interest in her.

As well as conflict with non-related household members, [earlier research](#) has shown that women who live with their husband's family tend to argue with their partners more and are also more likely to get divorced. Additionally, rates of domestic violence are [higher](#) when women live away from their genetic family.

But how does this relate to the severity of menopause symptoms? We think that increased levels of household conflict would result in the woman being more stressed. [Stress](#) is known to worsen pain perception and so could aggravate menopause symptoms.

In contrast to women who leave their kin group, women who live with their own family once they're married also tend to have higher levels of [social support](#). There are more people to help with childcare and more shoulders to cry on. This can help to lower stress and thus soften the mental and physical burden of the menopause.

## Global perspectives

While our research was conducted in China, globally, we see a wide range of living arrangements, which themselves can bring different levels of [conflict](#) and social support. In the West, many [women](#) live away from their families, which may mean that they lack social support, perhaps contributing to more turbulent menopause symptoms. Distance from one's own family can also be seen to increase [conflict](#) within the household—be it between a husband and wife, or wife and in-laws.

These results aren't an excuse to visit your in-laws less, but they show that menopause symptoms are not only about hormonal irregularities. They may also be a product of your social environment, which should be worth bearing in mind when approaching and going through the [menopause](#).
