

Most youth with chronic fatigue syndrome undiagnosed

February 20 2020

Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) remains

largely undiagnosed in youth, according to a study published online Jan. 23 in the *Child & Youth Care Forum*.

Leonard A. Jason, Ph.D., from DePaul University in Chicago, and colleagues assessed the prevalence of pediatric ME/CFS from an ethnically and sociodemographically [diverse community](#)-based random sample of 10,119 youth (aged 5 to 17 years) from 5,622 households.

The researchers found that the prevalence of pediatric ME/CFS was 0.75 percent. A higher percentage of those diagnosed were African-American and Latinx versus Caucasian. Of the youth diagnosed with ME/CFS based on the screening, less than 5 percent had been previously diagnosed. African-American and Latinx youth were twice as likely to have undiagnosed ME/CFS.

"Our finding that most youth with ME/CFS have not been previously diagnosed is comparable to findings in adults," a coauthor said in a statement. "We definitely need better ways to identify people with this illness and to develop effective interventions for them."
