Italian scientists want the government to conduct psychological tests on a sample of the population to determine how long people can stay confined to their homes, a report said Monday.

The Corriere della Sera newspaper said scientists want to understand how long Italians "are able to endure a lockdown" in the face of the coronavirus pandemic.

Prime Minister Giuseppe Conte will announce a new set of social guidelines this week that could include the tests, the report said.

Italy entered into a progressively more restrictive lockdown over the first half of March that has since been replicated by most European nations.

The Mediterranean country's 60 million citizens have been barred from walking more than 200 metres (650 feet) from their homes without a significant reason.

Reports of domestic abuse have surged and scientists worry about the impact of such isolation on the elderly and the more vulnerable.

Conte's government is now debating how it can lift the stay-at-home order and reopen businesses while there is still no coronavirus cure or vaccine.

The virus has officially killed 23,660 in Italy—second only to the United States—and probably many more because most care [home](#) deaths are not counted.

Conte is expected to let people out of their homes for more reasons when the current [lockdown](#) rules expire on May 4.
