Early-life respiratory illnesses may play a role in the greater odds of childhood asthma among Puerto Ricans, according to a new study from researchers at CUNY SPH and the University of California, San

Francisco.

The study, published in the journal *PLOS One*, examines the association between early-life respiratory illnesses such as pneumonia, bronchitis, and bronchiolitis/RSV within the first two years of life and physician-diagnosed asthma after the age of two in a large cohort of Puerto Rican, Mexican American, and African American children. While early-life respiratory illnesses were associated with greater odds of having asthma across the cohort, these associations were stronger among Puerto Rican children.

Puerto Ricans are among the populations most severely affected by asthma in the world. Approximately 23.6% of Puerto Ricans report they currently or previously had asthma, compared to 18.1% of African Americans, 9.5% of non-Hispanic whites, and 9.6% of Mexican Americans. Puerto Ricans are also four times more likely to die of the disease than non-Hispanic whites.

"Our results suggest that while all groups have greater odds of having asthma after respiratory infections, some groups are more affected than others," said CUNY SPH Distinguished Professor Luisa N. Borrell, the study's corresponding author. "Particularly in the Puerto Rican population, we note that [viral infections](#) may be a major driver of childhood [asthma](#) compared to other groups."

"The difference in outcomes highlights the need to examine heterogeneity within groups such as racial/[ethnic groups](#) as that may shed light in our understanding of health inequity," Borrell adds.

Borrell notes that the study cannot establish a cause-effect relationship and to address this issue, the research team is actively enrolling a large longitudinal birth cohort study of 3,000 Puerto Rican mother-infant pairs.
