

Immune from chronic stress? Limit inflammatory signaling to specific brain circuits

June 4 2020

A reporter protein, tdTomato, in a coronal section of the brain containing hippocampus. Researchers engineered the tdTomato in the IL-1R gene so the expression of IL-1R can be visualized. In addition to expression in endothelial cells, which forms vasculature, the image shows IL-1R in the dentate gyrus (resembling teeth, hence dentate), on both side of the brain. The dentate IL-1Rs are on neurons, allowing the inflammatory cytokine IL-1 to directly signal these

neurons. Credit: Florida Atlantic University

Anxiety and depression are significantly heightened during times of great stress such as the COVID-19 pandemic. Unfortunately, psychosocial stress is a major contributing factor to anxiety and depression. There is evidence that stress is associated with increased inflammation—increases in inflammatory cytokines, circulating monocytes, and microglial activation, which are detected in patients with anxiety and mood disorders.

Chronic [stress](#) has long been associated with the pathogenesis of psychological disorders such as depression and [anxiety](#). Recent studies have found [chronic stress](#) can cause neuroinflammation: activation of the resident immune cells in the brain, microglia, to produce inflammatory cytokines. Numerous studies have implicated the inflammatory cytokine, interleukin-1 (IL-1), a master regulator of immune cell recruitment and activity in the brain, as the key mediator of psychopathology. However, how IL-1 disrupts [neural circuits](#) to cause behavioral and emotional problems seen in psychological disorders has not been determined.

A groundbreaking study by neuroscientists at Florida Atlantic University and The Ohio State University, published in the journal *Molecular Psychiatry*, is the first to identify a role of the neuronal receptor for IL-1 (nIL-1R) in psychological disorders. Researchers demonstrate that nIL-1R straddles the intersection between social stress, inflammation, and anxiety in rodent models of stress.

The study shows for the first time that neuronal IL-1Rs in the hippocampus, a brain structure connected to learning and memory, is necessary and sufficient to mediate some of the behavioral deficits caused by chronic stress, pointing to a critical neuroimmune mechanism

for the etiology of these types of disorders. Findings from the study augment the understanding of IL-1R signaling in physiological and behavioral responses to stress and also suggest that it may be possible to develop better medications to treat the consequences of chronic stress by limiting inflammatory signaling not just generally, which may not be beneficial in the long run, but to specific brain circuits.

"We created and validated a unique genetic mouse model to restrict IL-1R1 expression to different cell types to visualize and control IL-1Rs," said Ning Quan, Ph.D., lead author, a professor of biomedical science in FAU's Schmidt College of Medicine, and a member of the FAU Brain Institute (I-BRAIN). "We demonstrated that chronic [social stress](#) caused the mice to show social withdrawal and working memory deficits. These changes could be prevented if the neuronal IL-1R1 was deleted and restored if IL-1R1 was only allowed to be expressed on [hippocampal neurons](#)."

For the study, researchers wanted to determine the degree to which IL-1 acts directly on hippocampal neurons to influence cognitive and mood changes with stress. To define the IL-1R-mediated neuronal response, they used novel and comprehensive IL-1R transgenic/reporter lines in which one can selectively delete IL-1R or restore IL-1R on specific cell types, including glutamatergic neurons. They also used modified viruses to manipulate hippocampal neurons and investigate the role of IL-1R in eliciting behavioral responses to stress. Their data show that social defeat-induced IL-1R signaling in hippocampal neurons perpetuated inflammation and promoted deficits in social interaction and working memory.

The research team previously detailed how [psychosocial stress](#) results in peripheral immune activation, increased levels of circulating monocytes, and robust neuroimmunological responses in the brain. These responses include increases in IL-1 and other [inflammatory cytokines](#), activation of

brain glial cells and movements of peripheral immune cells to the brain, along with enhanced activity of specific neuronal pathways. The work makes it clear that inflammatory-related effects of stress are not just global effects, but are associated with increased IL-1 signaling within specific [brain](#) circuits.

According to the Anxiety and Depression Association of America, nearly 40 million people in the United States (18 percent) experience an anxiety disorder in any given year. Globally, the World Health Organization (WHO) notes that 1 in 13 people suffers from anxiety. Anxiety disorders are the most common mental disorders worldwide with specific phobia, major depressive disorder and social phobia being the most common anxiety disorders.

"We are experiencing unprecedented levels of stress that will likely have long-lasting effects on millions of people of all ages around the world. When psychosocial stress becomes chronic, the effects are not just emotionally debilitating, they also are physically debilitating and can lead to high blood pressure, heart disease and even addictive behavior," said Randy Blakely, Ph.D., executive director of FAU's I-BRAIN. "Findings from this cutting-edge study will assist scientists and clinicians to develop more tailored treatments and therapies for people who struggle with anxiety, depression and other psychological [disorders](#)."
