

# Transplant patient recovers from COVID-19 after receiving donated plasma

June 30 2020

---

Within days of receiving the convalescent plasma treatment—an antibody-rich fluid donated by COVID-19 survivors—Edgardo Diaz tested negative for the virus and was released from the hospital. Credit: Edgardo Diaz

A year after his successful lung transplant, Edgardo Diaz, 30, found himself back in the hospital with COVID-19. Feverish and with failing kidneys, his condition quickly became critical.

Running out of time and options, Diaz's doctors at the University of Chicago Medicine invited him to participate in one of the hospital's COVID-19 [clinical trials](#) where he'd receive convalescent plasma—an antibody-rich fluid from the blood of people who have already survived COVID-19.

Diaz, an Oak Forest resident, is believed to be the first [lung](#) transplant patient in the world to receive convalescent plasma for COVID-19. He might even be the first person worldwide with any type of transplant to receive the COVID-19-fighting plasma, said Assoc. Prof. Remzi Bag, medical director of UChicago Medicine's lung transplant program and one of Diaz's doctors.

Within hours after receiving the convalescent plasma on April 25, Diaz's 104-degree fever started going down. Days later, his breathing and kidney function improved. Nine days after receiving the plasma, Diaz tested negative for COVID-19. He was released from the hospital May 1, and continues to test negative for the virus.

Now that he's home, Diaz said he feels "even better than I did before I had COVID-19." He's been able to resume his workouts, and has returned to his job.

Diaz stayed in close contact with his transplant team throughout the whole process. They knew his lung transplant disqualified him from most COVID-19 trials. But because he had severe and possibly life-threatening COVID-19, he met the FDA criteria for UChicago Medicine's plasma trial, said Asst. Prof. Maria Lucia Madariaga, who heads up the trial and was one of Diaz's lung transplant surgeons.

Despite Diaz having a suppressed [immune system](#) from his lung transplant, his doctors decided that the convalescent plasma would be a low-risk treatment for him—just as low-risk as it is non-[transplant](#)

patients.

"It's a pretty safe therapy," Madariaga said, adding that early reports she's seen nationwide about giving convalescent plasma to COVID-19 patients have shown very few side effects. "We have given it to high-risk, immunocompromised patients, and it still seems safe."

Unlike most hospitals in the U.S., which buy blood from a private company, UChicago Medicine has its own blood bank with more than 100 plasma donations from former COVID-19 patients to aid the clinical trial.

"For a disease like COVID-19, with so many unknowns, it's great that we're able to offer this and other clinical trials," Bag said.

Bag doesn't believe this [convalescent plasma](#) treatment will work for everyone, although it seems like a promising treatment for some patients.

"I don't think we have enough evidence," Bag said. "We need to more vigorously study the treatment. You get great results in some patients and not in others. Edgardo did remarkably well."

Researchers are still studying COVID-19, but it appears similar to a viral pneumonia in the lungs. It causes an overactive immune response, attacking the lungs and kidneys, and causing infection and inflammation in the body. If the immune system doesn't or can't respond to the virus, it can be deadly, Bag said.

When someone is infected with COVID-19, the body's immune system produces proteins called antibodies that, in most cases, will seek out and neutralize the virus. They provide the immune system extra resources to fight off the infection. Those antibodies then stay in the blood and

provide immunity. That's why the plasma from COVID-19 survivors is valuable to those who are very ill.

COVID-19 isn't disproportionately infecting [lung transplant](#) patients—they are equally susceptible as the general population, Bag said. They may be even more protected, because they're very cognizant of infections, and have practiced mask-wearing, social distancing and [hand washing](#) following their transplants, long before COVID-19 came along.

As for Diaz, he's continuing to wear a mask, wash his hands often, and take extra precautions not to catch germs.

"Everybody's different, but the [plasma](#) did pretty well with me and I think it'll do well with someone with new organs, also," Diaz said. "I beat [coronavirus](#)! At this point, nothing's going to stop me."

Anyone over the age of 18, who had a documented case of COVID-19 and has been symptom-free and healthy for more than 14 days, is encouraged to [donate plasma at UChicago Medicine](#).
