

Genetic analysis links obesity to higher rheumatoid arthritis risk

September 23 2020

An analysis of genetic data collected from more than 850,000 individuals of European ancestry has found a link between obesity-related genes and rheumatoid arthritis.

In the *Arthritis & Rheumatology* analysis, investigators found an increased risk of rheumatoid arthritis when body mass index was predicted to be high based on an individual's genetics. This was observed for both men and [women](#).

"These results highlight an important role of obesity in the pathological development of rheumatoid [arthritis](#), as well as provide a potential actionable preventive strategy," said senior author Xia Jiang, Ph.D., of the Karolinska Institute, in Sweden. "Future studies are needed to understand the biological mechanisms underlying such a link, and to understand how obesity may causally influence [rheumatoid arthritis](#) prognosis."
