

Probiotic skin therapy improves eczema in children, study suggests

September 9 2020

An experimental treatment for eczema that aims to modify the skin microbiome safely reduced disease severity and increased quality of life for children as young as 3 years of age, a National Institutes of Health study has found. These improvements persisted for up to eight months after treatment stopped, researchers report Sept. 9 in *Science Translational Medicine*.

Atopic dermatitis, commonly called [eczema](#), is a [chronic inflammatory skin disease](#) characterized by dry, itchy skin and rashes. The disease is most common in [children](#) and is linked to an [increased risk](#) of developing asthma, hay fever and food allergy. While available treatments can help manage eczema symptoms, current options can be costly, and many require multiple daily applications.

The [experimental therapy](#) contains strains of live *Roseomonas mucosa*—a bacterium naturally present on the skin—originally isolated from healthy volunteers and grown under carefully controlled laboratory conditions. For four months, clinical trial participants or their caregivers periodically applied this probiotic [therapy](#) to areas of skin affected by eczema.

"A child suffering from eczema, which can be itchy, painful and distracting for the child, also is very difficult for the entire family," said Anthony S. Fauci, M.D., director of NIH's National Institute of Allergy and Infectious Diseases (NIAID), which led the study. "These early-stage findings suggest that *R. mucosa* therapy may help relieve some children of both the burden of eczema symptoms and the need for daily treatment."

Numerous genetic and environmental factors contribute to eczema, and scientists are learning more about the role that the skin's microbiome plays in this condition. [In 2016](#), NIAID researchers reported that *R. mucosa* strains isolated from healthy human skin improved outcomes in

cell culture and mouse models of eczema.

To build on these preclinical findings, NIAID launched a Phase 1/2 clinical trial at the NIH Clinical Center in Bethesda, Maryland, to assess the safety and potential benefit of *R. mucosa* therapy in people with eczema. [Interim results](#) reported in 2018 for 10 adults and five children aged 9 to 14 years indicated that the treatment was safe and associated with reduced eczema severity. Since then, the trial has enrolled an additional 15 children, for a total of 20 children with mild to severe eczema ranging in age from 3 to 16 years.

Topical application of *Roseomonas mucosa* was associated with clinical improvement of atopic dermatitis in 15 children. The improvement may be related to lipid production by the bacteria which influence TNFR2-mediated epithelial repair through influences on nicotinic acetyl choline signaling and flagellar recognition. Twice weekly for three months and every other day for an additional month, children or their caregivers sprayed a solution of sugar water containing live *R. mucosa* onto areas of skin with eczema. For the first 15 children enrolled in the study, the dose of live *R. mucosa* was gradually increased each month. The last five children to enroll received the same dose throughout the four-month treatment period. Regardless of dosing strategy, no serious adverse events were attributed to the therapy.

"Most children in the study experienced substantial improvements in their skin and overall wellbeing following *R. mucosa* therapy. Encouragingly, the therapeutic bacteria stayed on the skin and continued to provide benefit after therapy stopped," said NIAID's Ian Myles, M.D., principal investigator of the trial. "These results support a larger study to further assess the safety and effectiveness of this [experimental treatment](#) by comparing it with a placebo."

Seventeen of the 20 children experienced a greater than 50% improvement in eczema severity following treatment. Improvement occurred on all treated skin sites, including the inner elbows, inner knees, hands, trunk and neck. The scientists also observed increases in the skin's barrier function—its ability to seal in moisture and keep out allergens. Additionally, most children needed fewer corticosteroids to manage their eczema, experienced less itching, and reported a better quality of life following the therapy. These benefits persisted after treatment ended, and the therapeutic *R. mucosa* strains remained on the skin for up to eight months.

The NIAID researchers next set out to better understand how *R. mucosa* therapy improves eczema symptoms. They found that treated skin had increased microbial diversity and reduced levels of *Staphylococcus*

aureus—a bacterium known to exacerbate eczema.

In addition to imbalances in the microbiome, the skin of people with eczema is deficient in certain lipids, or oils. By conducting experiments in cell and animal models of eczema, the NIAID scientists found that a specific set of lipids produced by *R. mucosa* strains isolated from healthy skin can induce skin repair processes and promote turnover of skin tissue. Study participants had increased levels of these lipids on their [skin](#) after treatment with *R. mucosa*.

The researchers emphasize that additional studies are needed to further elucidate the mechanism of *R. mucosa* therapy and to explore whether genetic or other factors may explain why some participants did not benefit from the experimental treatment.

More information: "Therapeutic responses to *Roseomonas mucosa* in atopic dermatitis may involve lipid-mediated TNF-related epithelial repair" *Science Translational Medicine* (2020).
