Researchers at the Institut de Recerca Sant Joan de Déu (IRSJD) in collaboration with those at Center for Genomic Regulation (CRG) have discovered that RING1B is a critical gene for the development of Ewing sarcoma, a rare type of developmental cancer that presents in bones and soft tissues. This newly uncovered epigenetic vulnerability in Ewing sarcoma cancer cells opens the door for new therapeutic strategies.

Ewing [sarcoma](#) is caused by a chromosomal translocation, where the EWSR1 gene in chromosome 22 fuses with most commonly the FLI1 gene in chromosome 11. The resulting EWSR1-FLI1 fusion protein, which contains the transcriptional activation machinery of EWSR1 and the DNA-binding domain of FLI1, is the main driver of tumorigenesis.

A new study published today in *Science Advances* describes how the oncogenic EWSR1-FLI1 fusion protein is directed to the different parts of the genome by RING1B, allowing EWSR1-FLI1 to hijack the transcriptional program of the [cells](#), turning them into [cancerous cells](#).

Researchers found that RING1B and EWSR1-FLI1 localize at the same regions in the genome, where RING1B is responsible for EWSR1-FLI1 recruitment. EWSR1-FLI1 cannot activate its [target genes](#) and transform a cell from healthy to cancerous state without RING1B, as shown by impaired tumor growth when RING1B is reduced.

Epigenetic inhibitors have been previously proposed to treat Ewing sarcoma and other types of pediatric cancers such as neuroblastoma, rhabdomyosarcoma or synovial sarcoma. Further research could explore the pharmacological inhibition of RING1B as a clinical therapy to treat Ewing sarcoma.

"Our findings offer striking insights into the mechanism of Ewing sarcoma, helping us get closer to uncovering the elusive cell-of-origin for this rare type of [cancer](#)," says Luciano Di Croce, researcher at the Center for Genomic Regulation and one of the authors of the study. "All we have to do is look for high levels of RING1B."

"EWSR1-FLI1 remains a challenging druggable target, therefore understanding its dependencies may offer alternative strategies to switch off its aberrant transcriptional program," says Sara Sánchez-Molina, first author of the study and postdoctoral researcher at the Institut de Recerca Sant Joan de Déu.

"Ewing tumors are paradigmatic examples of developmental cancers, where the first hit (genetic or epigenetic) occurs during [embryonic development](#) (gestation) and, in the majority of Ewing sarcomas, develops postnatally during specific stages of growth like puberty. The study supports the model by which embryonic stem cells characterized by high levels of RING1B are capable to sustain the aberrant transcriptional program caused by the oncogenic fusion protein. Ewing sarcoma will develop if the individual is born with precursor cells bearing the fusion oncoprotein," says Jaume Mora, scientific director of the Pediatric Cancer Center Barcelona-Institut de Recerca Sant Joan de Déu, and director of the study.

**More information:** RING1B recruits EWSR1-FLI1 and cooperates in the remodeling of chromatin necessary for Ewing sarcoma tumorigenesis. *Science Advances* (2020). [DOI: 10.1126/sciadv.aba3058](https://doi.org/10.1126/sciadv.aba3058)
