

Disparities in lung cancer screening eligibility still exist

January 25 2021

(HealthDay)—Despite increases in lung cancer screening eligibility,

gender, racial, and ethnic screening disparities may still persist, according to a study published online Jan. 12 in *JAMA Network Open*.

Thomas J. Reese, Pharm.D., Ph.D., from the University of Utah in Salt Lake City, and colleagues used data from the Behavioral Risk Factor Surveillance System (2017 to 2018) to identify adults (aged 50 to 80 years) with a smoking history in 19 states that used the optional lung cancer screening module. Change in eligibility among female, male, Black, Hispanic, and White participants (40,869 individuals) was examined before and after the U.S. Preventive Services Task Force revised [eligibility criteria](#).

The researchers found that the revised criteria increased eligibility for men (29.4 to 38.3 percent), women (25.9 to 36.4 percent), White individuals (31.1 to 40.9 percent), Black individuals (16.3 to 28.8 percent), and Hispanic individuals (10.5 to 18.7 percent). However, the odds of eligibility were lower for women versus men (adjusted odds ratio, 0.88) and for Black (adjusted odds ratio, 0.43) and Hispanic populations (adjusted odds ratio, 0.70) versus Whites.

"These findings suggest that screening disparities may persist among women and racial/ethnic minority populations with the revised guideline," the authors write.
