

# Brain organoids help to uncover various mechanisms of virus-induced microcephaly

April 9 2021

---

Human Brain Organoids (HBO) stained for the human neural progenitor cell (hNPC) marker Sox1 (magenta) showing infection by Zika virus (left, green) and by Herpes Simplex Virus 1 (HSV-1, right, in green). These models were used to uncover the mechanisms used by these two viruses to cause microcephaly during pregnancy. Credit: Krenn/CellStemCell/IMBA

Institute of Molecular Biotechnology of the Austrian Academy of Sciences have demonstrated that different viruses can lead to brain

malformations through diverse mechanisms by using human brain organoid models. The results are published in the journal *Cell Stem Cell*.

Microcephaly, a term referring to developmental malformations of the fetal brain, can be caused by diverse infections during pregnancy. The [infectious agents](#) in question are grouped under the general term of TORCH pathogens, in reference to Toxoplasma gondii, Other, Rubella, Human Cytomegalovirus (HCMV), Herpes Simplex Viruses 1 and 2 (HSV-1 and HSV-2), as well as the more recently emerged Zika virus (ZIKV), which was also added to the group. The question of whether all TORCH pathogens lead to microcephaly through the same mechanism has remained obscured due to the absence of suitable experimental models. Now, a team of researchers around IMBA Scientific Director Jürgen Knoblich provides the first comparative analysis of mechanisms linked to virus-induced microcephaly using a human brain [organoid](#) (HBO) [model](#) derived from human pluripotent stem cells (hPSCs).

"The two major difficulties in researching these conditions are, first, the delicate topic of testing noxious effects on fetal brain development during pregnancy which, understandably, prevents direct research on human fetuses, and second, the unsuitability of laboratory animal models, as they are neither the natural hosts of the viruses nor do they represent an accurate model of human brain development. To this end, our group was able to compare 3D human brain organoid models infected with different viruses. These infection models give us the closest possible insight into the human brain developmental outcomes of the viruses we study, and help us dissect the underlying structural, cellular, transcriptional and immunological parameters," explains first author Veronica Krenn, a postdoctoral researcher in the Knoblich group at IMBA.

In the present study, the researchers are able to bypass these difficulties and gain precious insights on phenotypes reminiscent of microcephaly in

organoids. Krenn and her colleagues do so by infecting 3D HBO cultures with TORCH viruses such as ZIKV and HSV-1 and demonstrate that both ZIKV and HSV-1 spread in organoids and halt their growth by promoting cell death. Through [transcriptional profiling](#), the team shows a unique feature of HSV-1 infection in organoids, namely a propensity to impair their neuroepithelial identity. Another major finding is that, although both ZIKV and HSV-1 attenuate the Type I interferon (IFN) immune response system in organoids, they appear to do so through different mechanisms, as is made evident by rescue experiments using distinct Type I IFNs.

The findings highlight the distinct paths used by various TORCH viruses to cause microcephaly and reveal complex cellular immune defenses, such as a neuroprotective role of various Type I IFN responses. The importance of these findings also resides in their unique observation in 3D brain organoid cultures, and not in 2D culture systems, thus stressing the superiority of HBO models in reproducing [virus](#)-induced neuropathological conditions and their relevance in studying the mechanisms of viral infections.

Taken together, this new research from the Knoblich lab presents organoid infection models that could help test therapeutic agents against ZIKV and HSV-1 infections and better dissect the human interferon responses. "By specifically infecting organoids with viruses, we can not only learn a great deal about the critical [brain](#) development interactions that are typically complex in humans. We will also be able to better target weak points of these viruses to find possibilities for new therapies," summarizes IMBA Scientific Director Jürgen Knoblich, the corresponding author of the study.
