

Sustained COVID-19 vaccine willingness in Denmark following rare cases of blood clots

April 9 2021

Nine out of ten Danes say that they will accept the COVID-19 vaccine when offered. This acceptance rate is at the same level as before the AstraZeneca vaccine was paused.

This is shown by a questionnaire-based survey collected by Søren Dinesen Østergaard and co-authors. He is professor at the Department of Clinical Medicine at Aarhus University and affiliated with the Department of Affective Disorders at Aarhus University Hospital, Psychiatry.

"In February 2021, we asked a sample of Danes whether they were willing to be vaccinated against the [coronavirus](#), and 89 per cent replied that they would. This picture was unchanged when the same people were asked again after the pausing of the AstraZeneca vaccine," says Søren Dinesen Østergaard.

The approximately 1,500 participants answered the questions about vaccination for the first time in the period between 4-21 February and then again in the period between 15-25 March. Danish health authorities paused the use of the AstraZeneca vaccine on 11 March—initially for 14 days before extending it until 9 April.

The survey also shows that many Danes feel insecure about the safety of the AstraZeneca vaccine. On a scale from 0-10, where ten is the safest, AstraZeneca scored just over five on average, while the vaccine from Pfizer scored above eight. As could be expected, it is those who do are not willing to be vaccinated who feel most insecure about the AstraZeneca vaccine after the reported blood clots.

"The fact that 89 percent still maintain that they willing to be vaccinated testifies to the high degree of trust in the Danish healthcare system. The extended pause indicates that the healthcare system is thoroughly investigating the cases of blood clots and thus takes our safety seriously. I think the population sees this as due diligence. If anything, it will probably increase confidence in the healthcare system," says Søren Dinesen Østergaard.

On the other hand, the research group is uncertain that all the people who say they are willing to be vaccinated will actually roll up their sleeves for the jab. It is well-known from survey research that 'good behavior' is often over-reported, because people give what they think is the 'right' answer. A phenomenon called social desirability bias.

"If this bias plays a role here, it likely means that the vaccine willingness has been overestimated in this study, but probably to the same extent before and after the pausing of the AstraZeneca vaccine," says Søren Dinesen Østergaard.

According to the researchers, the low level of confidence in the safety of the AstraZeneca vaccine is an important signal to the health authorities.

"The results indicate that there will be a need to rebuild the population's trust in the AstraZeneca vaccine if its use is resumed," he says. So far, more than 140,000 Danes have received the AstraZeneca vaccine. The Danish Medicines Agency is currently investigating reports of blood clots in combination with a low number of blood platelets occurring among individuals having received the AstraZeneca [vaccine](#). One case in Denmark has had a fatal outcome, and this case resembles several deaths elsewhere in Europe.
