The death of a spouse is a devastating event that can affect many aspects of the surviving partner's life. Sleep loss that often follows can have a negative long-term impact on the health of the widowed spouse,

according to new research from Rice University.

"Socioeconomic disparities in [health](#): Changes in [sleep quality](#) and inflammation during bereavement" will appear in the August edition of the journal *Comprehensive Psychoneuroendocrinology*. Lead author Lydia Wu, a psychology graduate student at Rice, and Christopher Fagundes, associate professor of psychology and principal investigator for the Biobehavioral Mechanisms Explaining Disparities (BMED) lab at Rice, led the research team.

"We already know from existing research that widowed [spouses](#) are at greater risk of heart problems or [death](#), especially in the months following the loss of their partner," said Wu. "We also know that death of a spouse can dramatically affect sleep quality of surviving loved ones. We wanted to see whether changes in sleep were linked to changes in immune health in surviving partners."

The researchers examined bloodwork and questionnaires evaluating sleep quality, health and demographic information three and six months after the death of spouses from 106 study participants. They found a significant link between increased sleep disruption and increased levels of bodily inflammation (confirmed by the presence of pro-inflammatory cytokines in the bloodstream).

They also found that the immune health of less educated people was more sensitive to changes in sleep quality than those with higher levels of education. In addition, surviving spouses with less education showed greater volatility in inflammation levels when sleep quality worsened or improved than those with more education. Inflammation is a key player in the development of many age-related diseases, including [cardiovascular disease](#).

"We are finding again and again that sleep quality plays a major role in a

person's health," Fagundes said. "This study adds to existing research showing that socioeconomic differences can exacerbate the health risks of grieving individuals."

The researchers hope the study results will lead to the creation of interventions to help improve the sleep and therefore the health of surviving spouses.
