Patients with HPV-related oropharyngeal cancer who undergo surgery and are treated with chemotherapy, may be able to forgo significant

radiation therapy without increasing the risk of their cancer spreading, according to the results of a clinical trial led by researchers at Mayo Clinic.

"We found that decreasing the amount of [radiation therapy](#) after a minimally invasive robotic surgery improved the quality of life of patients with HPV-related oropharyngeal cancer while delivering excellent cure rates," says Dr. Eric Moore, a Mayo Clinic otolaryngologist. "In essence, we found exactly the right amount of treatment to deliver without over-treating these patients."

Dr. Moore and his colleagues compared 79 patients treated at Mayo Clinic for HPV-related tonsil and tongue cancer with surgery and two weeks of radiation therapy to a group of 115 patients with the same cancer who were treated with surgery, and the standard six weeks of radiation therapy and chemotherapy.

Dr. Moore and his colleagues found no decrease in survival or [cancer](#) recurrence in the group that received two weeks of radiation therapy, compared to the group that received six weeks of radiation therapy. He says that by decreasing the amount of radiation therapy after minimally invasive robotic [surgery](#), physicians were able to improve the quality of life of patients and achieve excellent cure rates.

"In essence, we found exactly the right amount of treatment to deliver without overtreatment," says Dr. Moore.

Dr. Moore says Mayo Clinic now offers dose de-escalation radiation therapy to appropriately selected patients with HPV-related cancers of the tonsils and tongue.

"This approach shortens the treatment time for these [patients](#) by several weeks and reduces side effects without sacrificing the effectiveness of

the treatment," Dr. Moore says.
