

Allergic stimulation activates mast cell precursor cells

September 27 2021

Fig 1. Representative picture of an isolated mast cell progenitor before and after IgE-crosslinking. The immature cytoplasmic granules are stained by a fluorescent compound (yellow). Upon IgE-mediated crosslinking, the cytoplasmic granules fuse with the plasma membrane and the fluorescence is lost, indicating cell activation. Credit: Uppsala University

Mast cell precursor cells do not just cause an increase in mature mast cells during inflammation, they also play an active role in diseases like asthma. This finding is in a new study by immunology researchers published in the *Journal of Allergy and Clinical Immunology*. The study also emphasizes that precursor cells in general can play an active role in inflammation and challenges the current idea that only mature immune cells are involved in immune reactions.

"We have shown that mast cell [precursor cells](#) are activated immunologically when they are exposed to allergic stimulation. They can produce the cytokine IL-13, known to contribute to asthma development," says Erika Mendez-Enriquez, an immunology researcher at Uppsala University.

Mast [cells](#) are rare [immune cells](#) found in tissues that come into contact with the [external environment](#), such as the airways and the skin. Unlike other immune cells, mast cells develop from precursor cells that migrate to the tissues through the blood. Mast cells play a detrimental role in the development of asthma and allergies, mainly through their expression of the high-affinity receptor for IgE, the main antibody related to [allergic reactions](#). Mast cells become activated when IgE bound to the IgE receptors binds to allergens and releases substances that trigger physiological reactions such as the contraction of the airways in allergic asthma.

Mast cell precursors are extremely rare in healthy individuals, but their frequency increases during inflammation, which later causes an increase in mature mast cells. It is well documented that mast cells increase with many types of inflammatory diseases.

"Our previous studies demonstrated that, during acute inflammation, mast cell precursor cells dominate over the mature [mast cells](#) in number. The mast cell precursor cells in both mice and humans also have IgE receptors. For this reason, we wondered if the mast cell precursors can also be activated through allergic stimulation, and in our new study we have been able to confirm this. In the future, we will study if and how different types of asthma treatments impact mast cell precursor cells," says Jenny Hallgren Martinsson, Senior Lecturer in Immunology at Uppsala University and the leader of the study.
