

Newly approved PET imaging agent solves clinical dilemmas in breast cancer patients

September 29 2021

Determination of ER status of disease. In 59-y-old woman diagnosed with ER-positive lobular BC 2 y previously and treated with tamoxifen, ER-positive bone metastases were identified 1 y after initial diagnosis. She was treated with first-line endocrine therapy in palliative setting. Thereafter, disease became progressive and palbociclib was added. However, after 2 wk of treatment, she presented with pancytopenia. ¹⁸F-FES PET was performed to determine whether bone metastases were still expressing ER and whether there was a rationale for another line of endocrine therapy. Increased ¹⁸F-FES uptake could be seen in lymph nodes above and below diaphragm and in multiple bone lesions (e.g., spine, costae, scapulae, sternum, and pelvis) (A, maximum-intensity-projection image; B, PET/CT sagittal view; C, PET/CT transversal view of left

axillary region; D, PET/CT transversal view of pelvic region with positive inguinal lymph node). In addition, bone marrow involvement was visible. Diagnosis was settled on ER-positive metastatic disease, clinical dilemma was solved, and another line of endocrine therapy could be considered. However, because of bone marrow involvement, chemotherapy was indicated to achieve therapeutic effect more rapidly. Credit: J Boers and A.W.J.M. Glaudemans, University Medical Center Groningen

A non-invasive, patient-friendly imaging technique can help physicians make treatment decisions for breast cancer patients when diagnostic dilemmas arise. The ^{18}F -FES PET scan—approved by the U.S. Food and Drug Administration in 2020—was shown to solve 87 percent of dilemmas, providing physicians with information for personalized treatment decision-making. This research was published in the September issue of *The Journal of Nuclear Medicine*.

A key characteristic of breast cancer is the [estrogen receptor](#) (ER), which is expressed by 79 percent of breast tumors. Breast tumors that are ER-positive are likely to respond to hormonal therapy. To assess the presence of the ER, a biopsy of a [tumor](#) or metastases is commonly performed. However, clinical dilemmas may arise when a biopsy cannot be performed safely or when discrepancies in ER expression is suspected between tumor lesions.

" ^{18}F -FES PET has the potential to visualize the ER expression of all tumors across the body, and could provide helpful information regarding clinical dilemmas in [breast cancer patients](#)," noted Carolina P. Schröder, MD, Ph.D., medical oncologist at the University Medical Center Groningen in The Netherlands. "In our study, we evaluated whether ER clinical dilemmas could be solved by ^{18}F -FES PET findings."

The [retrospective study](#) reviewed 100 ^{18}F -FES PET scans that were

performed on 83 patients with three types of clinical dilemmas. These dilemmas included the inability to determine the extent of disease with the standard workup, unclear ER status of the tumor, or the inability to determine which primary tumor caused the metastases.

The clinical dilemma was solved by ^{18}F -FES PET in 87 percent of scans. In 93 percent of the solved cases, a treatment decision was based directly on the ^{18}F -FES PET result. The frequency of solved dilemmas was not associated with the type of dilemma. However, the frequency of solved dilemmas was related to ER status, as dilemmas in ER-positive scans were more likely to be solved than in ER-negative scans.

"This is the largest study to show the value of ^{18}F -FES PET in a 'real daily clinical practice,'" said Schröder. "These findings support the use of ^{18}F -FES PET for optimal patient outcomes and may support broad implementation of ^{18}F -FES PET in clinical practice."
