

What level of antibody response protects against COVID-19 death?

October 6 2021

In a study of patients with COVID-19 being treated in intensive care units, people who mounted only a low antibody response against the

SARS-CoV-2 virus faced a higher risk of dying.

The study, which is published in the *Journal of Internal Medicine*, also found that patients with strong antibody responses against the virus had low levels of viral RNA in their blood. On the contrary, those with poor antibody responses had high viral RNA levels and disseminated [viral proteins](#) in the blood.

The results could help establish the optimal antibody levels needed for an individual to overcome COVID-19 when critically ill. The study also provided evidence of the importance of antibodies against the spike protein of SARS-CoV-2 to block the virus' replication. These are the antibodies that are induced by vaccination.

"Our findings support that treatment with exogenous antibodies in COVID-19 should be personalized, reserving this therapy for those patients with absent or low endogenous [antibodies](#) levels", said co-senior author Jesús F. Bermejo-Martin, MD, Ph.D., of the Instituto de Investigación Biomédica de Salamanca (IBSAL) & CIBERES, in Spain.

Low anti-SARS-CoV-2 S antibody levels predict increased mortality and dissemination of viral components in the blood of critical COVID-19 patients
