

Can COVID vaccine technology help make a better flu jab?

October 15 2021, by Marie-Morgane Le Moel

Drugmakers are rushing to apply what has been learned about Covid jabs to the flu.

Winter is coming to the northern hemisphere, and with it the flu season—however advances spurred by the fight against COVID-19 are

boosting hopes of finding a more reliable vaccine.

Flu jabs have long been available to fight off the seasonal [virus](#), but their rate of effectiveness can vary from between 40 and 70 percent.

They work by injecting an inactivated virus strain into humans to trigger immunity. That inactivated virus must be prepared well in advance, and this can cause problems if the strains don't match up.

But now drugmakers and laboratories are rushing to apply what has been learned about RNA jabs to the flu, motivated by the potential not only for more effective, life-saving vaccines but also the vast profits up for grabs.

RNA, or [ribonucleic acid](#), is the lesser-known cousin of DNA, or deoxyribonucleic acid, the building block of genes.

Last month US pharmaceutical firm Pfizer began injecting humans with a [flu vaccine](#) that uses messenger RNA (or mRNA), which it already uses in its coronavirus vaccine.

Moderna, a US biotech company that makes a rival COVID vaccine using mRNA, launched its own flu jab trials in July.

And French drugmaker Sanofi has started trials on a "monovalent" RNA vaccine—which means it targets a single strain of virus—and will begin trials on a "quadrivalent" vaccine next year.

Immunologist Claude-Agnes Reynaud said that six months before [flu season](#)—"we assess which strains are circulating the most".

"Sometimes we get it wrong, and this creates a significant excess of mortality," said the director of research at France's INSERM health and

medical research institute.

"The problem with inactivating a virus to prepare a vaccine is that it can damage certain surface proteins," she added—and it is those same proteins that trigger the [immune response](#).

95 percent effective?

Instead of carrying these virus proteins into the body, lab-generated mRNA tells human cells to create them, so that the [immune system](#) can recognise and fight a future infection.

The World Health Organization advises vaccine makers which strains of flu they should track.

"And if it warns of a change in the prevalent strains, we will be able to change much faster with RNA" technology, said Jean-Jacques Le Fur, analyst at Bryan, Garnier & Co.

On that basis, the effectiveness of the vaccines could be increased to as much as 95 percent, the researcher said.

So the race is on to develop RNA-based flu vaccines.

Norbert Pardi, a vaccine specialist at the University of Pennsylvania, has used mRNA to formulate several antigens in a single vaccine.

Antigens cause immune systems to produce antibodies, and Pardi hopes his approach, already tested on mice, will "induce protection from multiple, diverse flu [strains](#)".

"Such multivalent vaccines will likely induce broadly protective immune responses superior to currently used flu vaccines," he told AFP.

However the technology does pose additional problems, such as the need to be stored at very low temperatures, unlike current flu vaccines that can be kept in regular refrigerators.

For drugmakers, the prospect of producing an mRNA [vaccine](#) to ward off the flu is an appealing one, said Jamila El Bougrini, a biotech specialist at stock market analyst Invest Securities.

The market for flu jab sales hit \$5 billion in 2020, and this year could reach up to \$7 billion.

It is "a very attractive market for the big laboratories", Bougrini said.
