

Identification of gene networks involved in uterine cancer could lead to better treatment options

January 28 2022

Clemson University researchers Allison Hickman and Alex Feltus identified 11 high priority genes associated with uterine cancer. Credit: 123RD.com

No single gene causes uterine cancer, the fourth most common cancer among women, which is on the rise in the U.S.

That's why Clemson University geneticist Allison Hickman's research focused on identifying networks of [genes](#) involved in [uterine cancer](#) that could be potential targets for more effective drug therapies.

The American Cancer Society estimates that nearly 66,000 women in the U.S. receive uterine [cancer](#) diagnoses this year. More than 12,500 women will die from the disease in 2022.

Using data from publicly available genomic databases, a mathematics-based distribution algorithm and Knowledge Independent Network Construction (KINC) software developed by her professor Alex Feltus in collaboration with Clemson alumnus and current Washington State University Assistant Professor Stephen Ficklin, Hickman built condition-specific biomarker systems for normal uterine tissue and two subtypes of uterine cancer—[endometrial cancer](#), the most common type, and uterine carcinosarcoma, which is more rare, aggressive and deadly.

These systems allow for a more comprehensive look into the biological networks and pathways affected in uterine cancer than single-gene analyses done in previous studies.

"We're looking for patterns. In this study, we were able to distinguish genes that had different relationships in uterine cancer than they did in normal uterine tissue," said Hickman, who earned her Ph.D. in genetics from Clemson in December. "The ultimate goal is to gain a better understanding of what's happening biologically at the [cellular level](#) in these cancers so it can lead to better treatment in the future."

No one gene determines whether a person will develop cancer. Rather, it's a complex system of genes.

Hickman's study found 11 high priority genes associated with uterine cancer. Those genes are potential targets for drug therapies.

"If you know what's broken, you can fix it," said Feltus, a professor in the College of Science's Department of Genetics and Biochemistry. "We have the power now, for the first time in the history of science, to look at the entire system and find the pieces that are broken and then to begin to fix them."

"It's not about finding the silver bullet for one gene," Feltus continued. "It's about finding the cocktails from a treatment perspective for sets of genes."

Feltus used a spider web as an analogy. If you want to get rid of the web, you can clip one strand of the spider web, but it's not likely to go away. But if you hit enough points on the spider web, the web will collapse.

The work of Hickman and other researchers in the field is important because scientists can see if therapeutics approved for other types of cancer target the same "broken genes."

"Ultimately, and this is the true holy grail, if we know there are x number of broken genes in a patient's uterine cancer, we can adjust those genes with small doses of drugs that target all of those broken genes at the same time as opposed to with one giant nuclear bomb of poison like a lot of cancer drugs we have right now," Feltus said.

"One hundred years from now, there will be drugs that interact with most of the genes, so you'll be able to design cocktails based on the genetic profile of the tumor," he said.

Hickman first compiled data from two online public databases for genomic information: The Cancer Genome Atlas and the National Institutes of Health Genotype-Tissue Expression (GTEx) project. She used Gaussian mixture models to build condition-specific gene co-expression networks for endometrial cancer, uterine carcinosarcoma and

normal uterine tissue. She then incorporated [uterine](#) regulatory edges and investigated potential co-regulation relationships.

Hickman said that approach allowed for analysis of genes involved in more than one biological process and therefore have multiple expression patterns.

An article published in *G3-Genes Genomes Genetics* titled "Identification of Condition-Specific Biomarker Systems in Uterine Cancer" describes Hickman's research. Other authors of the paper are Yuqing Hang and Rini Pauly.
