

Cannibal immune cells could offer new treatment path

February 22 2022, by Alison Bottcher, Peter Doherty

MHC II–C3dg complex formation and ubiquitination at the surface of cDCs

MZ B cells trogocytose from cDC pMHC II–C3 complexes for antigen presentation to CD4⁺ T cells

Marginal zone B cells trogocytose dendritic cells, acquiring peptide-loaded MHC II molecules bound to complement C3 for antigen presentation to CD4⁺ T cells. Activated complement C3 binds MHC II on conventional dendritic cells (cDCs). The complexes are processed into MHC II–C3dg and either internalized via MARCH1-mediated ubiquitination or recognized by the complement

receptor 2 (CR2) of marginal zone (MZ) B cells. The latter enables MZ B cells to trogocytose and display on their own membrane cDC receptors. Trogocytic MZ B cells expand their capacity to stimulate helper CD4+ T cells using antigen-loaded MHC II molecules generated by cDCs. Excessive trogocytosis eliminates cDCs, but MARCH1 prevents this by limiting the number of MHC II–C3dg complexes on cDCs. Credit: DOI: 10.1126/science.abf7470

Melbourne researchers have discovered that an immune cell, thought largely to be focused on fighting infection in newborns and infants, can in fact cannibalize the features of other immune cells, making it a potential new target for developing therapies across a range of infections.

Just published in *Science*, and a culmination of 15 years of work, the research by the Peter Doherty Institute for Infection and Immunity and the Bio21 Institute has found that so-called Marginal Zone (MZ) B cells can actually steal features from dendritic cells—the cells that act as sentinels alerting our [immune system](#) to infection.

If further research can uncover exactly how this happens then there is the potential for MZ B cells to be harnessed as a way to prompt more effective immune responses to specific infections.

"This finding is important because if we know what MZ B cells are really capable of doing, then we might be able to design vaccines or therapies to recruit them and boost our immune defenses," says University of Melbourne Professor Jose Villadangos, a laboratory head at the Doherty Institute and the Bio21 Institute and co-lead researcher on the paper.

MZ B cells, which produce antibodies that can attack a broad range of

infections, and dendritic cells that orchestrate the immune response both play highly important roles in the immune system, but until now it was believed they acted independently of one another.

"MZ B cells play a crucial role in protection against infection early in life, producing antibodies that can neutralize many types of bacteria in newborns and infants," explains Professor Villadangos.

"As we develop, other cells take over this function and become the most prominent contributors to long-lasting immunity, but we believe the MZ B cells retain unique capabilities that may be useful in the fight against certain pathogens at any time during life."

University of Melbourne Associate Professor Justine Mintern, a laboratory head at the Bio21 Institute and a co-author of the study, says the MZ B cell's contribution to immune defense was thought to be limited because they appeared unable to perform some critical functions.

"In particular, we thought they were unable to coordinate the actions of different immune cell types, an ability we considered only dendritic cells to have," says Associate Professor Mintern.

"Our research is contributing to change this perception, opening up new possibilities to harness the full potential of MZ B cells."

In their study, the researchers uncovered a new mechanism that enables MZ B cells to interact closely with dendritic cells and acquire the [membrane proteins](#) that allow dendritic cells to communicate with the foot soldiers of the immune system, T-cells, to trigger an immune response.

These membrane proteins, known as MHC molecules, are a highly specialized type of receptor that is exposed on the surface of dendritic

cells.

The researchers discovered that MZ B cells interact with dendritic cells through the innate immune system. This is the immune system we are all born with and which can attack a broad range of infections, but unlike our adaptive immune system, it can't change to attack other specific infections.

They found that a protein of the innate immune system called Complement C3 can bind with dendritic cells via the MHC receptors, and MZ B cells can then use these proteins to connect to [dendritic cells](#).

"We are the first to describe this association," says Associate Professor Mintern.

Dr. Patrick Schriek, lead author on the paper who was a Ph.D. student in Professor Villadangos' and Associate Professor Mintern's laboratories at the time, not only performed the key experiments that led to this discovery, but was also responsible for the next crucial finding.

"Once Complement C3 has bound to the MHC receptors, MZ B cells use their own receptor to specifically bind to C3 and draw the dendritic cell close," explains Dr. Schriek.

"Then, something remarkable happens: the MZ B cell rips the surface of the dendritic cell—their plasma membrane—and incorporates it into their own. It is a form of cellular cannibalism known as trogocytosis.

"The outcome is that the MZ B cell can now use the MHC molecules captured from a dendritic cell to communicate with T cells. Effectively, the MZ B cell can now pretend to be a dendritic cell."

The discovery has a surprising link to Laureate Professor Peter Doherty

himself, Patron and namesake of the Doherty Institute.

"This finding was unexpected and particularly satisfying for us because Peter Doherty was awarded the Nobel Prize in 1996 for first describing the function of MHC molecules," says Professor Villadangos.

"I have studied MHC molecules for over 30 years and I never expected we would stumble upon a new function carried out by these molecules, let alone that it would happen in an Institute named after Professor Doherty."

Professor Villadangos says "The next challenge is to figure out how to recruit MZ B cells, exploit their newly-found properties and harness their largely unexplored capabilities."

"Our laboratories are engaged in multiple collaborations with academic and industry partners, testing and improving new vaccine designs and immunotherapies."

"Ultimately the goal is to be able to use MZ B cells in a new way to fight [infection](#)," says Associate Professor Mintern.

"We may be able to develop more effective strategies to prevent or fight infections using vaccines that don't follow traditional rules but recruit cannibalistic MZ B cells to deliver new and improved outcomes."
