

Cause of metastasis in prostate cancer discovered

April 4 2022, by Johannes Angerer

KMT2C methyltransferase deficiency triggers metastatic dissemination of prostate cancer. a H&E stains of urinary tract obstruction by invasive PCa in a moribund Pten^{Δ/Δ} Kmt2c^{SETΔ/Δ} mouse at 39 weeks p.p. at low (top) and high

(bottom) magnification. Scale bars: 200 μm . T, tumor; U, urethra. b H&E-stained sections and IHC analysis of the androgen receptor (AR) and keratin 8 (KRT8) of tumor dissemination into lumbar lymph nodes, blood vasculature and lungs. Depicted material was derived from two moribund animals at 46- and 48-weeks p.p. Scale bars: 100 μm . LN, lymph node; L, lung; E, endothelial lumen; M, metastasis. c-d Percentage of wild type, $\text{Pten}^{\Delta/\Delta}$, $\text{Pten}^{\Delta/\Delta}\text{Kmt2c}^{\text{SET}\Delta/+}$ and $\text{Pten}^{\Delta/\Delta}\text{Kmt2c}^{\text{SET}\Delta/\Delta}$ mice presenting with lymph node (c) and lung (d) metastasis at the time of death. The number above the bar indicates metastasis-bearing/total number of analyzed mice ($n \geq 5$). e Kaplan Meier analysis depicting wild type, $\text{Pten}^{\Delta/\Delta}$, $\text{Pten}^{\Delta/\Delta}\text{Kmt2c}^{\text{SET}\Delta/+}$ and $\text{Pten}^{\Delta/\Delta}\text{Kmt2c}^{\text{SET}\Delta/\Delta}$ mice having developed metastasis at the time of death ($n \geq 5$). Mice that did not present with metastasis at the time of death are shown as censored events. The value below the dotted line indicates the median metastasis-free survival of $\text{Pten}^{\Delta/\Delta}\text{Kmt2c}^{\text{SET}\Delta/\Delta}$ mice. The P value was determined by a log-rank (Mantel-Cox) test. Credit: *Molecular Cancer* (2022). DOI: 10.1186/s12943-022-01542-8

Prostate cancers remain localized in the majority of cases, giving affected individuals a good chance of survival. However, about 20% of patients develop incurable metastatic prostate cancer, resulting in approximately 5,000 deaths each year in Austria alone. Medical research has not yet adequately explained why metastases occur in some people and not in others. A research team at MedUni Vienna has now discovered specific changes in a protein that drive the growth and spread of prostate cancer. The study was recently published in *Molecular Cancer*.

In the study, the researchers broke new ground and investigated the role of the protein KMT2C in prostate cancer. KMT2C is a genetic component that essentially functions as a regulator of central cellular processes. If KMT2C loses this regulatory ability due to typical cancer-related mutations, this encourages the proliferation of the cancer gene MYC. This in turn causes cells to divide at an increased rate, driving

both growth and spread of the cancer.

New insights into the transition to metastasis

"Our study provides new insights into the previously poorly understood transition from localized prostate cancer to terminal metastatic prostate cancer," says study leader Lukas Kenner (Department of Pathology at MedUni Vienna, Comprehensive Cancer Center of MedUni Vienna and University Hospital Vienna, Department of Laboratory Animal Pathology at Vetmeduni Vienna and the K1 Center CBmed), underlining the significance of the research work. In addition, the knowledge gained about the effects of KMT2C mutations may also generate new momentum for the diagnosis and treatment of prostate cancer.

Diagnosing aggressive progression at an early stage

KMT2C mutation status can be measured via a [blood test](#), allowing early diagnosis of potentially aggressive progression in [prostate cancers](#). In addition, MYC inhibitors could be used to prevent increased [cell division](#), and hence metastasis, and it is hoped that further scientific studies will substantiate this. MYC inhibitors are essentially new cancer treatment drugs that have already been tested in [clinical trials](#) and—if further studies confirm this—could also be used in metastatic [prostate cancer](#) in the next few years. "Since a high level of KMT2C mutation characterizes many types of cancer, such as breast, lung, colorectal, bladder and even skin cancer, our study results have a great deal of potential in the research, diagnosis and treatment of malignant cancers in general," says Lukas Kenner.
