

Best practices for iodinated contrast media shortage

May 12 2022

According to ARRS' *American Journal of Roentgenology* (*AJR*), to ensure that patients with emergent or life-threatening imaging indications can continue receiving care, radiology practice leaders need to quickly assess their contrast inventories, prioritize examination findings, and reduce overall iodinated contrast media (ICM) usage.

"Establishing awareness of the ICM shortage throughout the hospital system is an important first step," wrote coauthors Joseph Cavallo, MD, MBA, and Jay Pahade, MD, from the department of radiology and biomedical imaging at Yale's School of Medicine.

Alerting frequent referrers for CECT (ED, oncology, surgery) and concomitant users of ICM (cardiology, [vascular surgery](#), GI, [radiation oncology](#), urology) can align preservation strategies throughout the institution.

Additionally, common indications for CECT can be stratified, according to necessity, with three primary strategies for reducing ICM usage:

1. direct ICM dose reduction
2. alternative diagnostic imaging modalities or CT contrast agents
3. deferment of imaging

Drs. Cavallo and Pahade also provide examples of dose reduction that have been implemented at their institution—noting that the feasibility of any dose reduction depends on the specific equipment and imaging protocols at individual facilities.

"Unfortunately," the two *AJR* authors added, "departments may need to resort to deferment of CECT examinations." Ideally, rescheduling should be limited to certain low-risk examinations (i.e., annual staging examinations in patients without clinical evidence of recurrence), as well as follow-up examinations of incidental findings not posing an

immediate threat to the patient.

However, in the most critical of shortages, manual review of all pending CECT examinations may be necessary.

The unanticipated, albeit severe shortage in ICM currently affecting practices around the world is expected to continue into late June of this year.
