

Study lays foundation for new psoriasis treatment strategy

July 6 2022

Psoriatic-arthritis-like (PsA) phenotype in mice with severe psoriasis-like disease. (A) Prevalence of psoriatic arthritis (PsA) in mice with inducible dual epidermal deletion of *c-Jun* and *junB* (DKO*) and triple epidermal deletion of *c-Jun*, *JunB* and *S100A9* (TKO*) with severe psoriasis-like disease (n=20 per group). (B) Toluidine blue staining of the distal interphalangeal (DIP) joint of control wild-type (WT), DKO* and TKO* mice with PsA (scale bar=200 μ m). (C) Quantification of toluidine blue staining intensity of articular cartilage in WT, DKO* and TKO* mice (WT n=4; DKO* n=8; TKO* n=6; each point

represents the median of several joints measured per sample). (D) H&E-stained histological images showing psoriatic nail involvement with changes in the nail plate (P), nail matrix (M) and nail bed (B) of DKO* and TKO* mice and quantification of nail lesions (scale bar=100 μ m). (E) H&E histological images of the distal phalanx (DP) showing enthesitis with high immune infiltration in the areas around the bone (scale bar=100 μ m). (F) H&E histological images showing osteitis of the bone marrow (BM) of the distal phalanx (DP) in DKO* and TKO* mice (BM=bone marrow) with quantification of per cent area of bone marrow covered by inflammation (scale bar=100 μ m). About 250,000 people in Austria suffer from psoriasis. One third of them develop inflammation in their joints (psoriatic arthritis) as a result of the chronic skin condition. As part of a study, a MedUni Vienna research team has now discovered a key starting point for inhibiting inflammation in both psoriasis and psoriatic arthritis. The researchers' findings may form the basis for developing new treatment, diagnostic and prevention strategies. The study has now been published in the journal *Annals of the Rheumatic Diseases*.

The study conducted by the research group led by Erwin Wagner (Department of Dermatology and Department of Laboratory Medicine, MedUni Vienna) focused on the S100A9 gene, which has long been at the center of its internationally acclaimed scientific research into [psoriasis](#). The team has discovered that the severity of psoriasis (Ps) and psoriatic arthritis (PsA) can be reduced by inhibiting S100A9 systemically throughout the whole body rather than locally on the [skin](#).

With this finding, the MedUni Vienna researchers are laying the foundation for a [paradigm shift](#) in the treatment of Ps and PsA: "Our study is an important step towards the development of targeted therapeutic options in the form of drugs that act systemically rather than

locally on the skin," affirms Erwin Wagner. New diagnostic and prevention strategies can also build on the study.

Deciphered in preclinical experiments

Psoriasis is one of the most common chronic inflammatory skin conditions that can also spread to the joints. Triggers for the disease, which usually first appears in adulthood, include stress and UV radiation. However, individuals can also be genetically predisposed to developing Ps. S100A9 activation in skin and [immune cells](#) has been identified as a risk factor for the development of Ps and/or PsA.

As shown by previous basic research by Erwin Wagner's team at MedUni Vienna, the symptoms of psoriasis disappear when the S100A9 gene is deactivated in all cells of the body. The recent preclinical experiments were able to shed light on the particular influence that the skin and immune cells in which S100A9 is produced have on disease severity. "We now know that the [inflammatory responses](#) in psoriasis and [psoriatic arthritis](#) are enhanced when S100A9 is only inhibited in skin cells," Erwin Wagner explains, summarizing the main finding of the study. Therefore drugs inhibiting S100A9 have to be administered systemically in the form of tablets or drips.
