

Online atlas shows strong link between gut bacteria and metabolites

September 23 2022

The study is based on analyses of both fecal and blood samples from 8,583 participants in the Swedish CardioPulmonary bioImage Study (SCAPIS).

There are strong links between bacteria living in the gut and the levels of small molecules in the blood known as metabolites. This is the finding of a new study led by researchers from Uppsala University and Lund University, which is now published in the journal *Nature Communications*.

A team of scientists coordinated by Uppsala University and Lund University has found strong links between certain [bacteria](#) living in the gut and small molecules found in the [blood](#). The study is based on analyses of both fecal and blood samples from 8,583 participants in the Swedish CARDioPulmonary bioImage Study (SCAPIS). The findings have now been published for the first time in *Nature Communications*, and have further been made freely available to the research community through an online atlas. The aim of the project was to contribute to the expanding knowledge base concerning how [gut microbiota](#) influence human health.

"Earlier studies have shown that the large bacterial community in our digestive system produce a variety of molecules, with the potential to enter the bloodstream and to impact our health. Conversely, medication or dietary components may affect the microbiota composition before entering the circulation. Characterization of these interactions is an important step towards understanding the effects of the gut microbiota on health," says Tove Fall, Professor of Molecular Epidemiology at the Department of Medical Sciences and the Science for Life Laboratory, Uppsala University, who coordinated the study together with researchers from Lund University.

Recent technological advances have enabled large-scale deep characterization of bacterial communities in biological samples. This is done by sequencing the DNA content of the samples and comparing the results to DNA sequences from known bacteria. Advances in chemistry have further enabled large simultaneous screens of blood samples in

order to measure small molecules. The SCAPIS study represents one of the largest collections in the world of both of these kinds of data. In this study scientists investigated the links between the gut microbiota and the [small molecules](#) in the blood.

"The gut microbiota is a universe of its own and we have just started to understand how the human host and the bacterial community affect each other. Our results show that for certain blood [metabolites](#), the bacteria you carry in the gut constitute a strong determinant," notes Marju Orholm-Melander, Professor of Genetic Epidemiology, Lund University, and one of the senior authors of the study.

The scientific team believes that the breadth of findings may spur the interest of other international groups focusing on gut microbiota and host interactions, and has therefore opted to publish all the associations on a [public website](#) hosted by SciLife Data Centre in Uppsala.

"The large number of samples containing high quality data allowed us to identify many novel associations. We have therefore chosen to publish all of our findings in an online open resource for the research community to use for their varying needs," says Koen Dekkers, lead author from Uppsala University.
