

New horizons in neural recording systems

October 13 2022

ABILITY is a fully implantable neural recording system designed to amplify and wirelessly transmit high channel count, high frequency neural data from the brain to a computer in order to restore communication and independence for people with severe paralysis. Credit: Wyss Center

A new whitepaper, released by the Wyss Center for Bio and Neuroengineering, reveals the first neural signals recorded by the

ABILITY brain-computer interface (BCI) system. It also lays out the plan for a forthcoming human clinical trial with ABILITY to enable communication for people locked-in as a result of brain stem stroke or ALS (amyotrophic lateral sclerosis). The Wyss Center team, together with academic and clinical collaborators and a network of industrial technology partners, is developing ABILITY, a wireless implantable medical device, to improve quality of life and provide independence for people with paralysis.

Jonas Zimmerman, Ph.D., Senior Neuroscientist at the Wyss Center, explains that "neuroscience is experiencing a global renaissance. In recent years many talented research groups and industry leaders have developed new technologies ready to be tailored for people with severe paralysis. Now is the time to build on these achievements, overcome the final hurdles, and bring neural interface technology to those who need it most."

"The Wyss Center team and my lab are working together towards the same goal of restoring communication for people who are locked-in. We believe that future brain-computer interfaces will go far beyond current technology and have the exciting potential to bring new levels of independence to people with paralysis in their daily life," says Prof. Nick Ramsey from the UMC Utrecht Brain Center and Wyss Center collaborator.

George Kouvas, MBA, Wyss Center Chief Technology Officer says that "with fully implantable brain-computer interfaces still in their infancy, our approach at the Wyss Center is to offer a versatile system that not only connects to multiple electrode technologies, but that records [neural signals](#) from many channels at very high frequencies and wirelessly transmits the raw data using a high-speed optical link. In these early days, we believe that a versatile technology like ABILITY addresses the unmet needs of early adopters and, as a consequence, has the potential to

help the BCI market grow."

The whitepaper draws on experience from a recent clinical case study that successfully enabled BCI communication for a person completely locked-in because of ALS. It reviews existing methods of recording [electrical activity](#) from the brain and describes the clinical need for breakthrough implant technology. Finally, it describes the next steps to a [clinical study](#) that will not only assess the device performance but also the acceptance of implantable BCIs by patients, caregivers, and health care professionals.
