

Tumor hyaluronan as a novel biomarker in non-small cell lung cancer: A retrospective study

November 9 2022

Lung adenocarcinoma histochemistry. Representative sections illustrating tumor HA histochemistry staining (Ventana HA RxDx Assay) in FFPE lung adenocarcinoma samples scored as HA-low at 6X (A) and 11.2X (B) magnifications and HA-high at 6X (C) and 11.2X (D) magnifications. HA expression in the ECM of $\geq 25\%$ of the tumor surface area at any intensity was designated as HA-high. Credit: *Oncotarget* (2022). DOI:

Hyaluronan (HA) accumulation is associated with tumorigenesis and aggressive tumor behavior. In a new study, researchers Jun Gong, Michelle Guan, Haesoo Kim, Natalie Moshayedi, Sejal Mehta, Galen Cook-Wiens, Brent K. Larson, Jenny Zhou, Rishi Patel, Isaac Lapite, Veronica R. Placencio-Hickok, Richard Tuli, Ronald B. Natale, and Andrew E. Hendifar from Cedars-Sinai Medical Center and Memorial Sloan Kettering Cancer Center investigated the biomarker potential of HA in non-small cell lung cancer (NSCLC).

"The purpose of this study was to evaluate the significance of HA as a potential biomarker in NSCLC. Specifically, we investigated the prognostic and predictive value of [tumor](#) HA levels in a large cohort of predominantly advanced-stage NSCLC patients."

HA levels were scored using affinity histochemistry in 137 NSCLC samples stratified by HA score ≤ 10 , 11–20, 21–30, and >30 with HA-high defined as $\geq 25\%$ expression in the extracellular matrix (ECM) of the tumor surface area. Overall survival (OS) and time to progression from initiation of taxane therapy (TTP) were compared using log-rank tests based on HA score.

Of 122 patients with recurrent/metastatic NSCLC, 93 had mean HA scores that were not significantly different across clinicopathologic variables. Frequency of HA-high tumors did not differ by histology (34/68 adenocarcinomas vs. 12/25 squamous tumors, Fisher's $p = 1.0000$). Median OS for recurrent/metastatic adenocarcinoma was 35.5 months (95%, 23.6–50.3) vs. 17.9 months for squamous (95%, 12.7–37.0, log-rank test, $p = 0.0165$).

OS was not significantly different by HA quartiles, high or low (0.05). Median TTP (n = 98) significantly differed by HA quartile (2.8 months for HA score ≤ 10 ; 5.0 months for 11–20; 7.9 months for 21–30; 3.9 months for >30 , $p = 0.0265$). Improved TTP trended in HA-high over HA-low tumors (n = 98, $p = 0.0911$).

"In this NSCLC cohort, tumor HA level represents a potential biomarker for TTP, which remains a cornerstone of NSCLC therapy. Further validation is warranted to identify the HA accumulation threshold associated with clinical benefit," say the researchers.

The research was published in *Oncotarget*.
