

Tens of thousands of lives a year could be saved by new treatment protocol for brain hemorrhage

May 25 2023

Physiological measures from random assignment after treatment to day 7. Values are shown for patients with abnormal systolic blood pressure (A) and abnormal diastolic blood pressure (B) in 2905 (90.2%) of 3221 patients in the care bundle group and 3415 (90.7%) of 3767 patients in the usual care group; abnormal glucose (C) in 1094 (34.5%) of 3175 patients in the care bundle and 1319 (37.3%) of 3536 patients in the usual care group; and abnormal body

temperature (D) in 52 (1.6%) of 3214 patients in the care bundle and 68 (1.8%) of 3716 patients in the usual care group. Recordings were at 15-min intervals in the first hour after commencing treatment (time 0), hourly from hours 1 to 6, once every 6 h until 24 h, and twice per day until day 7. The overall means per treatment group and overall difference in variables between treatment groups at 1 h and at 24 h were calculated using a repeated-measure linear mixed model with a fixed effect of treatment, a fixed categorical effect of time, a fixed interaction between treatment and time, a repeated patient effect (to model within-patient correlations assuming a compound symmetry structure), and a random site effect, with adjustment for baseline measurements. R indicates time of random assignment. Credit: *The Lancet* (2023). DOI: 10.1016/S0140-6736(23)00806-1

Data from the phase III INTERACT3 study demonstrate that a new combination of treatments for stroke due to intracerebral hemorrhage (ICH) significantly improves the chances of surviving without major disability. Results were presented at the European Stroke Organization Conference in Munich, Germany, and published in *The Lancet*.

The INTERACT3 study is the first-ever randomized controlled trial to show a clearly positive outcome for the treatment of ICH. Timely administration of the new treatment protocol—known as a Care Bundle—centered on the rapid control of high blood pressure, led to improved recovery, lower rates of death, and better overall quality of life in patients with this serious condition.

Professor Craig Anderson, Director of Global Brain Health at The George Institute and a senior author of the research said, "Despite the high rates of ICH and its severity, there are few proven options for treating it, but early control of high blood pressure is the most promising. Time is critical when treating this type of stroke, so we tested a combination of interventions to rapidly stabilize the condition of these

patients to improve their outcomes. We estimate that if this protocol was universally adopted, it could save tens of thousands of lives each year around the world."

Commonly referred to as a [hemorrhagic stroke](#) or brain bleed, ICH is the second most common type of stroke and also the most deadly, with 40% to 50% of patients dying within 30 days. It occurs when blood leaks out of a blood vessel into the [brain tissue](#) and represents over a quarter of all cases of stroke, affecting approximately 3.4 million people a year.

In the INTERACT3 study, over 7,000 patients were enrolled across 144 hospitals in 10 countries—nine middle-income countries and one high-income country.

The research team evaluated the effectiveness of the new Care Bundle, which included early intensive lowering of [systolic blood pressure](#), strict glucose control, fever treatment, and rapid reversal of abnormal anticoagulation.

They found that using this new treatment protocol compared to usual care reduced the likelihood of a poor functional outcome, including death, after six months. This was estimated to prevent one additional death for every 35 patients treated.

Central to this was a rapid reduction in systolic blood pressure, where target levels were achieved, on average, in 2.3 hours (range 0.8 to 8.0hrs), compared to 4.0 hours (range 1.9 to 16.0hrs) in the control group. The interventional protocol resulted in a statistically significant reduction in mortality, number of serious adverse events, and time spent in hospital, as well as demonstrating an improvement in health-related quality of life.

The burden of ICH is greatest in low- and middle-income countries. In

2019, 30% of all stroke cases in LMICs were ICH, almost double the proportion seen in high-income countries (16%). This is in part due to high rates of hypertension and limited resources for primary prevention strategies, including identification and management of [stroke](#) risk factors by health care services.

Dr. Lili Song, joint lead author and Head of the Stroke Program at The George Institute China, said, "A lack of proven treatments for ICH has led to a pessimistic view that not much can be done for these patients. However, with INTERACT3, we demonstrate on a large scale how readily available treatments can be used to improve outcomes in resource-limited settings. We hope this evidence will inform clinical practice guidelines across the globe and help save many lives."
