

Study shows both men and women who are vegetarian face increased risk of hip fracture

July 31 2023

Both men and women who follow a vegetarian diet face a 50% greater risk of a hip fracture compared to people who regularly eat meat, according to the results of a large-scale study.

It has been recognized that women who are vegetarian have an elevated

risk of hip fracture, but the reasons why are unclear, and studies looking at the impact of a vegetarian diet on men have been small scale and inconclusive.

Researchers at the University of Leeds have analyzed data on 413,914 people—both men and women—and it gives the first indication that vegetarian men also face a greater risk of hip fracture than men who regularly eat [meat](#). It also identifies some of the factors that may be putting vegetarians—both male and female—at increased risk.

Recruited between 2006 and 2010, the individuals in the study—all part of the UK Biobank project—provided information on their diet and were classed as either a regular meat eater who ate meat five or more times a week; an occasional meat eater consuming meat fewer than five times week; pescatarian where they ate fish but not meat; or vegetarian where they could consume dairy foods but not fish or meat.

The data on the individuals was linked to their hospital records and a cases of hip fracture were recorded in the follow-up period to 2021.

The paper—Risk of hip fracture in meat-eaters, pescatarians, and vegetarians: a prospective cohort study of 413,914 UK Biobank participant—is published in the journal *BMC Medicine*.

Among the 413,914 participants, there were 3,503 cases of hip fracture, an overall incidence rate of less than one percent (0.8%).

Although the overall risk of having a hip fracture was low, the relative risk between vegetarians and regular meat eaters was large. The researchers found:

- Vegetarians had a 50% greater risk than regular meat-eaters, regardless of sex.

- There was no difference in risk between occasional and regular meat-eaters.
- Pescatarians had a slightly greater risk (8%) than regular meat-eaters, but this was a non-significant difference.

Diet group	Cases/participants	Person years		Unadjusted HR (95% CI)		Multivariable-adjusted HR (95% CI)
Regular meat-eater	2045/258765	3145791				
Occasional meat-eater	1310/137954	1678303		1.11 (1.04, 1.19)		0.99 (0.93, 1.07)
Pescatarian	78/9557	116983		1.32 (1.05, 1.66)		1.08 (0.86, 1.35)
Vegetarian	70/7638	93259		1.67 (1.31, 2.12)		1.50 (1.18, 1.91)

0.5 1.5 2 0.5 1.5 2

Risk of hip fracture in occasional meat-eaters, pescatarians, and vegetarians compared to regular meat-eaters in the UK Biobank. Both models controlled for age, and the multivariable-adjusted model was adjusted for the following (all at recruitment): region (England, Scotland, Wales), sex (male, female), ethnicity (white, black, Asian, mixed, other), Townsend deprivation index (continuous), live alone (yes, no), smoking (current, former, never), supplementation (yes, no), physical activity in MET-minutes per week (continuous), alcohol consumption in drinks per day (continuous), body mass index (continuous), number of children (0, 1, 2, ≥ 3), menopausal status (premenopausal, postmenopausal), hormone replacement therapy (current, former, never), diabetes (yes, no), cancer (yes, no), cardiovascular disease (yes, no), and other fracture (yes, no). HR (95% CI), hazard ratio (95% confidence interval). Credit: *BMC Medicine* (2023). DOI: 10.1186/s12916-023-02993-6

Relative risks—and real-world cases

The scientists calculated how these relative differences may translate to real-world cases.

They predicted on average 6.5 regular meat eaters and 6.5 occasional

meat eaters would experience a hip fracture, while there would be 7 cases among pescatarians and 9.5 cases among vegetarians.

James Webster, a doctoral researcher in the School of Food Science and Nutrition who led the study, said, "Hip fractures are a growing problem in an aging society, and can trigger debilitating [health conditions](#) and a loss of quality of life."

"This study shows that while vegetarians face a greater risk of hip fracture than meat-eaters—at 50%—this translates to just 3 more hip fractures per 1,000 people over 10 years. The health benefits of a vegetarian diet, including a lower risk of cancer and [cardiovascular disease](#), may still outweigh any increases in hip fracture risk."

"Our analysis suggests that low BMI may be a key factor in why their risk is higher."

"Additionally, vegetarians were about 17% less likely to meet protein recommendations than meat-eaters. So, important messages from our study are that vegetarians need to ensure they are getting a [balanced diet](#) with enough protein and maintain a healthy BMI. This will help vegetarians to maintain healthy bones and muscles."

Professor Janet Cade, who leads the Nutritional Epidemiology Group at the University of Leeds and supervised the research, said, "Hip fracture is a major health issue and diet may have a part to play in affecting risk."

"This research, using the large UK Biobank, confirms our previous work, showing that a vegetarian diet increases risk of hip fracture compared to regular meat eaters, in both men and women. While [vegetarian](#) diets have health benefits, understanding [diet](#) quality and the balance of key nutrients may help to reduce risk and improve future bone health."
