A new study published in the journal *JAMA Network Open* studies the connections between arsenic exposure and cardiovascular disease processes in children.

Led by Brooks B. Gump, Ph.D., M.P.H., the Falk Family Endowed Professor of Public Health in the Falk College, the research group considered arsenic exposure and <u>health data</u> of 245 children in the Syracuse, New York, <u>metropolitan area</u>. It is the first study to directly measure the associations between arsenic exposure and precursors to cardiovascular disease in children.

The study's findings are important because they highlight the need to reduce arsenic exposure in children. Arsenic is a naturally occurring element that can be found in soil and water. It can also be released into the environment from industrial activities.

In this Syracuse News Q&A, Professor Gump shares details about how this research can contribute to safer public health standards, and how arsenic exposure in children potentially accelerates the development of cardiovascular disease in <u>adults</u>.

# **Q:** Can you briefly explain your research findings related to arsenic exposure and the health impacts on children?

A: Arsenic was measured in urine as well as several measures of subclinical cardiovascular disease . This arsenic exposure was

significantly associated with some of the <u>health outcomes</u>, including increasing vascular "thickness" and heart changes. These particular cardiovascular changes can predict later disease. Given this was not a clinical trial (it would be unethical to purposively expose children to arsenic), we made a point of controlling for many other factors, such as poverty.

#### **Q:** How do you measure 'arsenic exposure?'

A: Arsenic exposure is best assessed using urine, as we did in this study. These levels are considered an indicator of cumulative but relatively recent <u>arsenic exposure</u>.

## **Q:** How do the results found in children compare to adults who have been exposed to similar conditions?

A: Adults have shown some of the same associations between arsenic and cardiovascular disease—this is the first study to document these associations in a group this young. However, it should be made clear that this is not actual disease but rather a risk factor for future disease (such as elevated cholesterol),

Cardiovascular disease develops very slowly, beginning at a very young age and potentially developing into a diagnosable disease later in life.

### **Q:** From a prevention standpoint, what can parents and caregivers do to protect their kids?

A: Given arsenic is now so commonly found in our environment, one of the best actions we can take is to first lower what is considered a "normal" level (
