

Black women weigh emerging risks of 'creamy crack' hair straighteners

August 7 2023, by Ronnie Cohen, KFF Health News

Deanna Denham Hughes was stunned when she was diagnosed with ovarian cancer last year. She was only 32. She had no family history of cancer, and tests found no genetic link. Hughes wondered why she, an

otherwise healthy Black mother of two, would develop a malignancy known as a "silent killer."

After [emergency surgery](#) to remove the mass, along with her ovaries, uterus, fallopian tubes, and appendix, Hughes said, she saw an Instagram post in which a woman with uterine [cancer](#) linked her condition to chemical [hair](#) straighteners.

"I almost fell over," she said from her home in Smyrna, Georgia.

When Hughes was about 4, her mother began applying a chemical straightener, or relaxer, to her hair every six to eight weeks. "It burned, and it smelled awful," Hughes recalled. "But it was just part of our routine to 'deal with my hair.'"

The routine continued until she went to college and met other Black women who wore their hair naturally. Soon, Hughes quit relaxers.

Social and economic pressures have long compelled Black girls and women to straighten their hair to conform to Eurocentric beauty standards. But chemical straighteners are stinky and costly and sometimes cause painful scalp burns. Mounting evidence now shows they could be a [health hazard](#).

Relaxers can contain carcinogens, like formaldehyde-releasing agents, phthalates, and other endocrine-disrupting compounds, according to National Institutes of Health studies. The compounds can mimic the body's hormones and have been linked to breast, uterine, and [ovarian cancers](#), studies show.

African American women's often frequent and lifelong application of chemical relaxers to their hair and scalp might explain why hormone-related cancers kill disproportionately more Black than white women,

say researchers and cancer doctors.

"What's in these products is harmful," said Tamarra James-Todd, an epidemiology professor at the Harvard T.H. Chan School of Public Health, who has studied straightening products for the past 20 years.

She believes manufacturers, policymakers, and physicians should warn consumers that relaxers might cause cancer and other health problems.

But regulators have been slow to act, physicians have been reluctant to take up the cause, and racism continues to dictate fashion standards that make it tough for women to quit relaxers, products so addictive they're known as "creamy crack."

Michelle Obama straightened her hair when Barack served as president because she believed Americans were "not ready" to see her in braids, the former first lady said after leaving the White House. The U.S. military still prohibited popular Black hairstyles like dreadlocks and twists while the nation's first Black president was in office.

California in 2019 became the first of nearly two dozen states to ban race-based hair discrimination. Last year, the U.S. House of Representatives passed similar legislation, known as the CROWN Act, for Creating a Respectful and Open World for Natural Hair. But the bill failed in the Senate.

The need for legislation underscores the challenges Black girls and women face at school and in the workplace.

"You have to pick your struggles," said Atlanta-based surgical oncologist Ryland Gore. She informs her [breast cancer patients](#) about the increased cancer risk from relaxers. Despite her knowledge, however, Gore continues to use chemical straighteners on her own hair, as she has since

she was about 7 years old.

"Your hair tells a story," she said.

In conversations with patients, Gore sometimes also talks about how African American women once wove messages into their braids about the route to take on the Underground Railroad as they sought freedom from slavery.

"It's just a deep discussion," one that touches on culture, history, and research into current hairstyling practices, she said. "The data is out there. So patients should be warned, and then they can make a decision."

The first hint of a connection between hair products and health issues surfaced in the 1990s. Doctors began seeing signs of sexual maturation in Black babies and young girls who developed breasts and pubic hair after using shampoo containing estrogen or placental extract. When the girls stopped using the shampoo, the hair and breast development receded, according to a study published in the journal *Clinical Pediatrics* in 1998.

Since then, James-Todd and other researchers have linked chemicals in hair products to a variety of health issues more prevalent among Black women—from early puberty to preterm birth, obesity, and diabetes.

In recent years, researchers have focused on a possible connection between ingredients in chemical relaxers and hormone-related cancers, like the one Hughes developed, which tend to be more aggressive and deadly in Black women.

A 2017 study found white women who used chemical relaxers were nearly twice as likely to develop breast cancer as those who did not use them. Because the vast majority of the Black study participants used

relaxers, researchers could not effectively test the association in Black women, said lead author Adana Llanos, an associate professor of epidemiology at Columbia University's Mailman School of Public Health.

Researchers did test it in 2020.

The so-called Sister Study, a landmark National Institute of Environmental Health Sciences investigation into the causes of breast cancer and related diseases, followed 50,000 U.S. women whose sisters had been diagnosed with breast cancer and who were cancer-free when they enrolled. Regardless of race, women who reported using relaxers in the prior year were 18% more likely to be diagnosed with breast cancer. Those who used relaxers at least every five to eight weeks had a 31% higher breast cancer risk.

Nearly 75% of the Black sisters used relaxers in the prior year, compared with only 3% of the non-Hispanic white sisters. Three-quarters of Black women also self-reported using the straighteners as adolescents, and frequent use of chemical straighteners during adolescence raised the risk of pre-menopausal breast cancer, a 2021 study in the *International Journal of Cancer* found.

Another 2021 analysis of the Sister Study data showed sisters who self-reported that they frequently used relaxers or pressing products doubled their ovarian cancer risk. In 2022, another study found frequent use more than doubled uterine cancer risk.

After researchers discovered the link with uterine cancer, some called for policy changes and other measures to reduce exposure to chemical relaxers.

"It is time to intervene," Llanos and her colleagues wrote in a *Journal of*

the National Cancer Institute editorial accompanying the uterine cancer analysis. While acknowledging the need for more research, they issued a "call for action."

No one can say that using permanent hair straighteners will give you cancer, Llanos said in an interview. "That's not how cancer works," she said, noting that some smokers never develop lung cancer, despite tobacco use being a known risk factor.

The body of research linking hair straighteners and cancer is more limited, said Llanos, who quit using chemical relaxers 15 years ago. But, she asked rhetorically, "Do we need to do the research for 50 more years to know that chemical relaxers are harmful?"

Charlotte Gamble, a gynecological oncologist whose Washington, D.C., practice includes Black women with uterine and [ovarian cancer](#), said she and her colleagues see the [uterine cancer](#) study findings as worthy of further exploration—but not yet worthy of discussion with patients.

"The jury's out for me personally," she said. "There's so much more data that's needed."

Meanwhile, James-Todd and other researchers believe they have built a solid body of evidence.

"There are enough things we do know to begin taking action, developing interventions, providing useful information to clinicians and patients and the general public," said Traci Bethea, an assistant professor in the Office of Minority Health and Health Disparities Research at Georgetown University.

Responsibility for regulating personal-care products, including chemical hair straighteners and hair dyes—which also have been linked to

hormone-related cancers—lies with the Food and Drug Administration. But the FDA does not subject personal-care products to the same approval process it uses for food and drugs. The FDA restricts only 11 categories of chemicals used in cosmetics, while concerns about health effects have prompted the European Union to restrict the use of at least 2,400 substances.

In March, Reps. Ayanna Pressley (D-Mass.) and Shontel Brown (D-Ohio) asked the FDA to investigate the potential health threat posed by chemical relaxers. An FDA representative said the agency would look into it.

Natural hairstyles are enjoying a resurgence among Black girls and women, but many continue to rely on the creamy crack, said Dede Teteh, an assistant professor of public health at Chapman University.

She had her first straightening perm at 8 and has struggled to withdraw from relaxers as an adult, said Teteh, who now wears locs. Not long ago, she considered chemically straightening her hair for an academic job interview because she didn't want her hair to "be a hindrance" when she appeared before white professors.

Teteh led "The Cost of Beauty," a hair-health research project published in 2017. She and her team interviewed 91 Black women in Southern California. Some became "combative" at the idea of quitting relaxers and claimed "everything can cause cancer."

Their reactions speak to the challenges Black [women](#) face in America, Teteh said.

"It's not that people do not want to hear the information related to their [health](#)," she said. "But they want people to share the information in a way that it's really empathetic to the plight of being Black here in the

United States."
