

Study supports potential for injectable 'chemical vaccine' for malaria using atovaquone

October 20 2023

Phenotypic characterization in vitro of isogenic wild type (WT) and cytochrome b Y268S mutant *P. falciparum*. **a** Cumulative number of asexual parasites in continuous culture. Growth rate of wild type parasites ($y = 0.35x + 9.3$) was 1.4-fold greater than that of mutant ($y = 0.21x + 7.9$); n timepoints = 36, $R^2 > 0.99$, data from one continuous experiment. **b** Atovaquone activity against WT or Y268S asexual erythrocytic parasites (EC_{50} 0.68 nM or 9.0 μ M, respectively) was obtained by assaying [3 H]hypoxanthine incorporation as a function of

atovaquone concentration. Depicted are mean \pm SD of quadruplicate determinations from each of three biological replicate experiments (for each data point $n = 12$; some SD are too small to extend outside the symbols); $R^2 \geq 0.994$. **c** Male gametocyte exflagellation, adjusted to 1.5% gametocytemia. *Bars*, median number of centers across four independent biological replicates (ranges 4 to 28 for WT, and 0 to 10 for mutant); n , the total number of fields examined; **** P
