Hair products often contain ingredients that easily evaporate, so users may inhale some of these chemicals, potentially posing health repercussions. Now, researchers have studied emissions of these volatile organic compounds (VOCs), including siloxanes, which shine and smooth hair.

The scientists report in [*Environmental Science & Technology*](#) that using these [hair](#) care products can change indoor air composition quickly, and common heat styling techniques—straightening and curling—increase VOC levels even more.

Some prior studies have examined the amounts of siloxanes released from [personal care products](#). But most focused on products that are washed off the body, such as skin cleansers, which might behave differently from products that are left on the hair, like creams or oils.

In addition, most previous studies on siloxane emissions haven't looked at the [real-time](#), rapid changes in indoor air composition that might occur while people are actively styling hair.

Nusrat Jung and colleagues wanted to fill in the details about VOCs released from hair products, especially in real-world scenarios such as small bathrooms where they're typically applied.

The researchers set up a ventilated tiny house where participants used their usual hair products—including creams, sprays and oils—and heated tools. Before, during and after hair styling, the team measured real-time emissions of VOCs including cyclic volatile methyl siloxanes (cVMS), which are used in many hair care products.

The [mass spectrometry data](#) showed rapid changes in the chemical composition of air in the house and revealed that cVMS accounted for most of the VOCs that were detected. Emissions were influenced by product type and hair length, as well as the type and temperature of the styling tool. Longer hair and higher temperatures released higher amounts of VOCs.

As a result of their findings, the researchers estimated that a person's potential daily inhalation of one cVMS, known as D5, could reach as

much as 20 mg per day.

In the experiments, turning on an exhaust fan removed most of the air pollutant from the room within 20 minutes after a hair care routine was completed, but the scientists note that this practice could affect outdoor air quality in densely populated cities. They say studies of the long-term human health impacts of siloxane exposure are urgently needed, because most findings are from animal studies.
