Researchers in the lab of chemist Han Xiao at Rice University have identified a promising new immunological pathway to treat stubborn

bone tumors, one of most prevalent forms of metastases in breast cancer patients.

"More than 70% of people with metastatic breast [cancer](#) will see the [cancer cells](#) move to bone, which can lead to skeletal-related events like bone pain, fractures, and hypercalcemia," said Yixian Wang, a Rice graduate student in the Han lab who is a lead author on a study [published](#) in *Proceedings of the National Academy of Sciences*.

"There are now several immunotherapies that can potentially benefit [breast cancer patients](#) with metastases, but they aren't effective in patients with bone tumors."

Each year, more than [240,000 new cases](#) of breast cancer are diagnosed in the United States, according to the Centers for Disease Control and Prevention. Approximately one-quarter of those patients will experience metastasis, where cancer cells spread from the breast to other parts of the body.

New immunotherapies called checkpoint inhibitors can uncloak stubborn tumors, allowing the immune system to send in powerful immune cells to deal with the abnormal cells. But while checkpoint inhibitors are effective for many patients, they do not work for everyone—and [clinical trials](#) have shown little to no response when used to treat bone metastases.

Xiao, associate professor of chemistry, biosciences, and bioengineering at Rice, said he and his team wanted to find another pathway that might be more effective in obliterating these stubborn bone metastases.

"We thought there must be another novel checkpoint axis we could target for the breast cancer cells in bone," Xiao said. "And we discovered a unique glyco-immune checkpoint axis in bone metastases that involves a protein called sialic acid-binding Ig-like lectin (Siglec)-15. We learned that it suppresses immune cells in the bone."

After noting that there was a significant upregulation of Siglec-15 in the

[tumor](#) microenvironment in bone tumor samples from breast cancer patients, Xiao and colleagues demonstrated that this receptor plays an important role in hiding bone tumors from the immune surveillance.

"Current FDA-approved checkpoint inhibitors are mediated by [protein-protein interactions](#) that suppress immune cells," Xiao explained.

"Siglec-15, however, is a glyco-immune checkpoint inhibitor. Instead of binding to a protein, Siglec-15 binds to the sugars you find on the cell surfaces—and that's how it can suppress the [immune system](#). This is an entirely new type of immune checkpoint that offers great promise for future treatment for bone cancers."

Xiao's team conducted several cell culture experiments to study Siglec-15 interactions in the bone tumor microenvironment. They learned it is involved in crosstalk between tumor cells and important [immune cells](#) like T-cells and macrophages, as well as bone-specific cells, osteoclasts.

"You can find these glycolipids and glycoproteins on all cells—and we know they play an important role in immune modulation," added Xiao. "These findings offer us an opportunity to study these glyco-immune checkpoint inhibitors more in depth and identify those that can help bone tumors stop evading immune recognition."

But simply modulating the behavior of Siglec-15 may be enough to treat bone metastases. When the team injected a monoclonal antibody that targets Siglec-15 into an animal model of [metastatic breast cancer](#) with bone tumors, they were able to trigger a powerful immune response. In fact, the researchers saw the tumors diminish after only one or two doses of the antibody therapy.

"It was really a striking finding," said Wang. "I'm very excited about the potential therapeutic outcome for a therapy like this. This could be a

very helpful treatment for breast cancer patients in the future."

Xiao said he and his team plan to continue studying the new and unique biology of glyco-immune checkpoint pathways in the [tumor microenvironment](#). He added there is still much to learn about these pathways and future studies should provide new biological insights with the power to improve both current and future immunotherapies.

In addition, Xiao said he would like to see if targeting Siglec-15 might be helpful in treating other kinds of cancers that affect [bone](#).
