

Study finds oral health indirectly influences subjective psychological well-being in older adults

January 30 2024

A new study has found that oral condition affects psychological well-being in older adults via its influence on nutritional status and a person's individual or environmental characteristics. Credit: Dr. Noriko Takeuchi from Okayama University, Japan

In humans, oral health influences general health and well-being in many ways. Other than reducing the need for oral rehabilitation later in life, maintaining good oral health reduces the risk of several systemic

diseases. Therefore, investing time and effort into improving oral health can be highly beneficial for older adults. However, whether the health benefits of improved oral health extend to psychological domains remains unclear.

Positive psychological well-being is known to positively affect the survival rates of both healthy and unhealthy populations. Thus, to increase [life expectancy](#), it is important to identify the factors associated with subjective well-being. This involves the evaluation of quality of life, which includes life satisfaction, interests, and happiness.

Now, a team of researchers led by Senior Assistant Professor Noriko Takeuchi from the Department of Preventive Dentistry, Okayama University Hospital, found that [oral health](#) influences subjective well-being in older adults through its effects on nutritional status and the individual's environment.

Additionally, Dr. Daisuke Ekuni from Department of Preventive Dentistry, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Dr. Nanami Sawada from Department of Preventive Dentistry, Okayama University Hospital, and Dr. Manabu Morita from Department of Oral Health, Takarazuka University of Medical and Health Care were involved in the research and served as co-authors in this study, published in [PLOS ONE](#).

The team examined oral conditions such as bacterial load in the tongue coating, chewing ability, swallowing ability, and more, among older adults visiting a [dental clinic](#) in Okayama University Hospital, and examined how these measurements are related to participants' self-reported psychological well-being. They also measured participants' nutritional status and environmental characteristics including [social connections](#), habits, and [medical history](#).

"The scientific evidence for the relationship between oral health and psychological well-being is limited. To overcome the limitations of the previous studies and as a step toward health promotion, we evaluated the association between individual and environmental characteristics, oral condition, and nutritional status in relation to subjective well-being among older adults," explains Dr. Takeuchi.

The findings of the study revealed that oral condition is related to nutritional status, which in turn, is related to subjective well-being among [older adults](#). Oral condition plays a significant role in determining the types of food that a person can consume. Therefore, an individual's oral condition may influence nutritional intake, thus influencing their health status.

"Maintaining good oral health can help improve nutritional status, which in turn, can improve subjective psychological well-being," says Dr. Takeuchi.

In addition, this study provides evidence for a bidirectional connection between oral health and a person's individual and social environment. This connection can be explained by the fact that poor social relations are associated with psychological stress leading to habits such as smoking and sweet consumption, thereby increasing the risk of cavities, gum disease, and tooth loss.

Moreover, it reports a connection between a person's environmental characteristics and nutritional status. Overall, the findings suggest that oral health may not directly influence the subjective well-being, but indirectly, through [nutritional status](#) or environmental characteristics.

In a time when Japan's population is aging rapidly, geriatric care is getting increased focus from health care providers in the country. The study provides crucial insights into how oral health exerts extended

effects on mental health and suggests that health care investment in oral health can have increasing health benefits, especially in old age.

"Our cross-sectional study has some limitations; however, the results highlight that good oral health may improve the subjective psychological well-being in the long run," concludes Dr. Takeuchi.
