As Canada's flu season collides with record strep A cases and ongoing COVID-19 concerns, a new study is shedding light on our understanding of respiratory immune responses. Scholars from the Research Institute of the McGill University Health Center (RI-MUHC) have discovered a surprising facet about a century-old vaccine for tuberculosis, *Bacillus Calmette Guérin* (BCG).

The study, [published](#) in the journal *Nature Immunology*, uncovered a previously unknown mechanism that extends the vaccine's shield to combat influenza A virus—the most prevalent flu strain.

"The immune interactions involved here can 'train' the lungs, which are frequently exposed to [infectious agents](#) in the environment. If we can map out the protective immune pathways involved in the lungs, this will revolutionize our conceptual and clinical approaches in developing vaccines against infections, including emergent respiratory viruses," explains lead author Maziar Divangahi, a pulmonary immunologist, a senior scientist at the RI-MUHC, and a Professor of Medicine at McGill University.

The discovery paves the way for future studies to assess whether BCG could be used to prevent other emergent viruses. Notably, research on the vaccine's protection against COVID-19 has had promising results.

More information: Kim A. Tran et al, BCG immunization induces CX3CR1^{hi} effector memory T cells to provide cross-protection via IFN- γ -mediated trained immunity, *Nature Immunology* (2024). [DOI: 10.1038/s41590-023-01739-z](https://doi.org/10.1038/s41590-023-01739-z)
