

Researchers develop an automated 3D-printed bioreactor to grow bone in the lab

May 23 2024, by Angela Nicoletti

Bone cells live in bone tissue in the body. But the cells in these images are carrying out their bone-building duties outside the body—inside a 3D printable device, called a bioreactor, created by FIU researchers.

Over the years, Florida International University (FIU) biomedical engineer Anamika Prasad has been refining the [device](#) with the help of her students, most recently master's student Paula Gustin. The result: A [design](#) with cylinder-shaped hollows that mimics the unique environment that [bone tissue](#) requires. And, most important, supports long-term survivability of samples.

In fact, new [published research](#) shows samples can survive in the device for up to 28 days. This can be a gamechanger for scientists who need to study cellular changes over longer periods of time to discover new drugs and therapeutics.

It can also help advance bone engineering research—including bone reconstruction to replace large chunks of bone lost to cancer, infections or injury—as well as cartilage research and growing new cartilage tissue.

Prasad also plans to use this device as a part of her other research, including an ongoing 3D bone reconstruction project with Dr. Juan Pretell, Chief of Musculoskeletal Oncology Surgery at Baptist Health.

Bioreactor Fabrication and Development

Polyactic acid or PLA is used to 3D print the bioreactor components.

Coating agents were applied to the printed parts to ensure a secure seal and a conducive tissue surface.

An peristaltic pump drives the flow and Arduino controlled DC motor drives the mechanical load.

Testing and Validation

fresh swine femur bone samples were cultured

Bone samples cores was placed inside tissue well.

Incubator for storage (37° Celsius and 5% CO₂)

Confocal microscopy for cell viability
