

Fatigue with rheumatoid arthritis tied to disease activity, education level

June 26 2024, by Lori Solomon

The Bristol Rheumatoid Arthritis Fatigue Multi-Dimensional Questionnaire (BRAf-MDQ) and Brief Fatigue Inventory (BFI-C) scores show consistency in assessing fatigue with rheumatoid arthritis

(RA), according to a study published online June 14 in *Immunity, Inflammation and Disease*.

Jun Zhou, from the Affiliated Suqian First People's Hospital of Nanjing Medical University in China, and colleagues assessed [fatigue](#) with RA by two scales and validated their consistency. The analysis included 160 patients with RA and 60 healthy controls.

The researchers found that the BRAF-MDQ and BFI-C scores were significantly elevated in RA patients versus healthy controls. There was a positive and significant correlation between BRAF-MDQ global fatigue score and BFI-C global fatigue score in both RA patients ($r = 0.669$) and healthy controls ($r = 0.527$). There was a high consistency between BRAF-MDQ and BFI-C global fatigue scores in RA patients ($W = 0.759$) and healthy controls ($W = 0.933$) using the Kendall's tau-b test. Higher education level ($B = -4.547$) and swollen joint count ($B = 1.965$) independently were associated with BRAF-MDQ global fatigue score. Higher education level ($B = -0.613$) and clinical disease activity index ($B = 0.053$) independently linked with BFI-C global fatigue score.

"Exploring the risk factors of fatigue for early management is of great significance for the treatment of RA patients," the authors write.
