Scientists at Van Andel Institute and Icahn School of Medicine at Mount Sinai have developed a potent anti-cancer compound that inhibits cancer cell growth in a tough-to-treat type of infant leukemia. The findings are <u>published</u> in the journal *Science Advances*.

The compound, MS-41, targets and destroys ENL, a protein that is essential to the progression of MLL-rearranged leukemia. Without ENL, leukemia cells lose the ability to proliferate and spread.

"Up to 80% of acute leukemias in infants are linked to problems with the MLL gene, yet there are few effective treatments for MLLrearranged leukemias," said VAI Professor Hong Wen, Ph.D., cocorresponding author of a study describing the findings.

"MS-41 is a new, experimental compound that effectively targets and degrades a central survival mechanism in leukemia cells. Our early results are promising, and we're excited to continue developing MS-41 as a potential <u>leukemia</u> treatment."

MS-41 belongs to a family of <u>cancer</u>-fighting compounds called PROTAC degraders, which are an increasingly popular approach to cancer drug development.

Unlike traditional small-molecule inhibitors, PROTAC degraders completely remove their <u>target proteins</u>, enabling them to deliver robust therapeutic effects at low doses with fewer side-effects. PROTAC degraders also often require less frequent treatment than other currently available cancer medications.

The findings also reveal that MS-41 did not harm healthy cells when tested in mouse models. Such compounds are desirable as medications because they are less likely to cause side effects.

Moving forward, Wen and her colleagues will investigate MS-41 in additional models to assess if it is applicable in other types of ENLrelated acute leukemias and cancer types such as Wilms tumor.
