

New insights into the pathogenesis of amyotrophic lateral sclerosis

August 28 2024, by Jill Adams

Prolonged imbalance in glucose metabolism increases RAN translation and accumulation of DPRs, heightening neuronal vulnerability in in vitro and in vivo models of C9orf72-ALS/FTD. C9-BAC mice show dysregulated brain metabolite production. Glucose homeostasis is critical to maintaining RAN translation of the C9 repeats at low levels. Neurons bearing the ALS/FTD causative C9orf72 mutation are more vulnerable to glucose deficiencies than wild-type neurons. Credit: *EMBO Reports* (2024). DOI: 10.1038/s44319-024-00140-7

The symptoms of amyotrophic lateral sclerosis (ALS)—a neurodegenerative disease that involves loss of nerve cells that control movement—tend to emerge in adulthood. To Davide Trotti, Ph.D., a neuroscientist at Thomas Jefferson University, this suggests that some unknown trigger causes a shift from a quiescent state to a biochemical storm causing neuronal death.

One hypothesized trigger is dysfunction of energy pathways in the central nervous system. The metabolism of glucose in the brain is altered in people with a specific ALS-linked genetic mutation, called C9-NRE, and this change occurs many years before the onset of muscle weakening that characterizes the disease.

Dr. Trotti and his collaborators embarked on molecular detective work to describe how altered energy metabolism is linked to neuronal dysfunction. In a recent paper, [published](#) in *EMBO Reports*, the team showed how altered [glucose metabolism](#) in the brain and [spinal cord](#) are damaging to [motor neurons](#) in preclinical models that carry the genetic C9-NRE mutation.

Neuronal dysfunction, in turn, further undermines energy pathways in a vicious cycle of stress responses. This feedforward loop of problems that the researchers observed in cell culture and in animal models likely plays a role in the neurodegeneration seen in ALS patients.

In carefully teasing out the [molecular pathways](#) involved, Dr. Trotti says he hopes to identify potential therapeutic targets whereby a drug might interrupt the chain reaction. The idea is to prevent the triggering event and hopefully stave off or slow down disease progression in patients with the genetic mutation.

"There are drugs on the market that can affect these processes," he says, "and they are already FDA approved." Dr. Trotti has hope for

medications that are prescribed for diabetes, a condition that also involves altered glucose metabolism. Testing such drugs in preclinical models is the next step to see if they correct the metabolic imbalance.
