

What we know about the new mpox outbreak

August 17 2024

A surging mpox outbreak in Africa was declared an emergency by the World Health Organisation this week and the European Centre for Disease Prevention and Control (ECDC), an EU agency, on Friday said

more imported cases to Europe were "highly likely".

The Africa Centres for Disease Control and Prevention (Africa CDC) declared its first-ever Public Health Emergency of Continental Security (PHECS) for the deadly disease.

It is the second time the WHO has issued its public health emergency warning since the epidemic first spread around the world in 2022.

Now the virus has crossed from its epicenter in the Democratic Republic of Congo to other African nations and was detected this week for the first time in Sweden and Pakistan.

What is mpox?

The disease, formerly known as monkeypox, was first detected in humans in the DRC in 1970.

There are two subtypes of the virus: clade 1 and clade 2.

The deadlier clade 1 has been endemic in the Congo Basin in central Africa for decades.

The less severe clade 2 has become endemic in parts of West Africa.

Mpox can spread human-to-human through sexual or close physical contact. Symptoms include fever, muscular aches and large boil-like skin lesions.

The virus gained international prominence in May 2022, when a less deadly strain called clade 2b spread around the world, mostly affecting gay and bisexual men.

Between January 2022 and June 2024, 208 deaths and more than 99,000 mpox cases were recorded across 116 countries, according to the WHO.

What is new?

The latest surge has been of the deadlier clade 1—and its new mutated variant.

The new strain, called clade 1b, was first detected among sex workers in the DRC in September 2023.

Sweden this week reported the first case of the variant outside of Africa, and the EU's health body urged countries to increase preparedness. Pakistan reported Asia's first case.

"It is not surprising... that travel between continents has brought this case to Europe," said Brian Ferguson, an Associate Professor of Immunology, University of Cambridge.

He added that cases were likely to spike in Europe and elsewhere as "there are currently no mechanisms in place to stop imported cases of mpox".

Containing the epidemic will require "rapid international co-operation", said Francois Balloux of the University College of London Genetics Institute—adding there was "no evidence of transmission in Europe at this stage".

Who is affected?

Clade 1 mpox is "known for causing more severe disease in young children, pregnant women, and immunocompromised people", said Jonas

Albarnaz, who specializes in pox viruses at the Pirbright Institute in Britain.

Clade 1b is driven by sexual transmission and mostly infects young adults, Albarnaz said.

It has also been recorded spreading through non-sexual contact between people, including children playing together at school.

Clade 1b causes death in around 3.6 percent of cases, though infants and children are more at risk, according to the WHO.

Where is affected?

More mpox cases were reported in the first half of this year than in all of 2023, according to WHO figures.

The majority of recent cases have been in the DRC, where 548 people have died so far this year, the government said.

Over the last month, previously unaffected countries such as Burundi, Kenya, Rwanda and Uganda have reported outbreaks, according to the Africa CDC. None have reported deaths, the WHO said.

Nigeria has flagged 39 cases of a milder strain of mpox this year, health officials said Friday.

Sweden and Pakistan this week reported the first mpox cases outside of Africa, with the WHO warning more cases of the new strain were likely in Europe.

Is there a vaccine?

During mpox's global spread in 2022, vaccines were deployed in Europe and North America which helped control the outbreak.

But vaccines have not been made widely available in the African countries most affected by mpox.

The US Department of Health said Wednesday it would donate 50,000 doses of an mpox vaccine to DRC.

On Tuesday, Africa CDC head Jean Kaseya announced an agreement with the European Union and Danish drugmaker Bavarian Nordic to distribute 200,000 doses across the continent.

Although that would not be enough, Africa could secure another 10 million vaccines, Kaseya told a media briefing.

Bavarian Nordic said Friday it was seeking European approval to use its mpox vaccine in children aged 12 to 17.
