

Brain rehearsal time ensures lasting memory performance

14 February 2012

University of Alberta researchers have established that the ability of the brain to rehearse or repeat electrical impulses may be absolutely critical in order to make a newly acquired memory more permanent.

U of A psychology professor Clayton Dickson likened the process to someone trying to permanently memorize a phone number, "We repeat the number several times to ourselves, so hopefully we can automatically recall it when needed."

Dickson, the lead researcher on the project, says that neurons likely rehearse the process for recalling newly installed memories by using the brain's downtime to send and resend signals back and forth, establishing well practiced synaptic connections. "Those connections allow the brain to retrieve the memories and rehearsal ensures that they last for a long time," said Dickson. "It was previously thought that only biochemical processes like [protein synthesis](#) were important for solidifying memories"

Dickson says further investigation of this process could be used to improve an individual's memory and possibly as a tool to delete negative or post [traumatic memories](#).

More information: The paper by graduate student Arjun Sharma and U of A colleagues Dickson and Frank Nargang was published February 14, in *The Journal of Neuroscience*.
