

# IVF success for one in two under 35, but failure after five cycles

30 August 2013

The first national report into the cumulative success of IVF has shown there is little chance of pregnancy after the fifth round of treatment, regardless of a woman's age.

The study is the first in the world to look at national success rates and is part of the report "Assisted [reproductive technology](#) in Australia and New Zealand 2011," produced by UNSW's National Perinatal Epidemiology and Statistics Unit.

The overall results, covering all [age groups](#), show that the chance of delivering a liveborn baby was 21.1% after the first cycle, increasing to 31.1% after two cycles, 36% after three cycles, 38.6% after four cycles, and 40% after five cycles, based on newly released statistics (2009-11) from 35 fertility centres.

The cumulative live delivery rate did not increase markedly with additional treatments in the sixth cycle and beyond. The sixth cycle only afforded an extra 0.7% chance of pregnancy and the seventh cycle, 0.4%.

The results include [women](#) seeking treatment across the age spectrum, from those under 30 to women over 45.

But for younger women, the results are more encouraging. More than half (50.6%) under 30 have a baby within five rounds of IVF and there are similar rates of success for women aged 30 to 34 (51.7%).

"This is a great result. It shows the benefit of getting treatment early," says Professor Elizabeth Sullivan, an author of the report and the head of UNSW's National Perinatal Epidemiology and Statistics Unit.

"The other good news is that we expect to see the cumulative success rates increase as women who may have only had one or perhaps two cycles in our study timeframe, return for further treatment – and get pregnant," she says.

"While more than 90% of the women undergoing treatment had fewer than five cycles during 2009-2011, there were 264 who had 10 or more cycles," she says.

## Women over 40

The report also shows the fastest growing group undergoing IVF is women 40 and above, with a quarter of the clinics' clientele being from this age group in 2011.

"This has been rising steadily from 14.3% in 2002 and 21.4% in 2007 to 25.3% in 2011," says Professor Sullivan.

The average age of women undergoing non-donor cycles in 2011 was 35.9 years.

## Assisted reproductive technology on the rise

The number of [assisted reproductive technology](#) (ART) treatment cycles performed in Australia and

New Zealand is also growing.

There were more than 66,000 ART treatment cycles performed in the two countries in 2011 (61,158 and 5,189 respectively). This represents an increase of 7.4% from 2010 and 16.8% from 2007.

The report also shows:

- The average age of women undergoing donor cycles was 40.8 years, with nearly two-thirds (65.4%) aged 40 years or older.
- The live delivery rate was above 18% for donor cycles in women aged 40 years or older, which is similar to the rates for [younger women](#).
- Male-only infertility makes up 22.5% of all problems reported by the clinics, compared with 28.5% for female-only infertility factors. 14.3% reported combined male-female factors; 22.7% reported unexplained infertility and 11.7% were not stated.

A continuing trend in ART treatment in Australia and New Zealand has been the reduction in the rate of multiple birth deliveries, decreasing from 10% to 6.9% between 2007 and 2011.

"Australia and New Zealand are leading the way – having the lowest regional rate of multiple birth deliveries in the world," says Associate Professor Mark Bowman, a fertility doctor and the president of the Fertility Society of Australia.

"This was achieved by a continuing shift in clinical practice to single embryo transfer, which has continued to increase from 63% in 2007 to 73% in 2011."

Importantly the substantial decrease in multiple deliveries had been achieved while the clinic pregnancy rate has remained stable, at around 23%.
