

Cellular defect may be linked to Parkinson's: study

8 September 2016

they start releasing waste, Wang and colleagues explained in a university news release.

The finding could lead to more accurate and earlier diagnoses of Parkinson's, as well as new treatments, the researchers said.

Parkinson's disease, a progressive disorder affecting the nervous system, is marked by tremors, stiffness and loss of balance and coordination. It affects one in every 60 to 70 Americans 65 and older.

The study was published online Sept. 8 in the journal *Cell Stem Cell*.

(HealthDay)—Researchers say they've discovered a cellular defect that may be common to all forms of Parkinson's disease.

The defect plays a major role in the die-off of a group of [nerve cells](#) whose loss is a hallmark of Parkinson's, according to the Stanford University team. The researchers conducted a series of experiments with cells from Parkinson's patients and [healthy people](#).

"We've found a molecular biomarker that characterizes not just familial cases of Parkinson's, in which a predisposition for the disease is clearly inherited, but also the condition's far more prevalent sporadic forms, for which the [genetic contribution](#) is either nonexistent or not yet discovered," said senior author Dr. Xinnan Wang, an assistant professor of neurosurgery.

This defect prevents cells from quickly eliminating their internal power sources (mitochondria) when they wear out. So instead of supplying energy,
