

Post-RFA mortality up for ESRD patients who receive dialysis

20 March 2017

non-dialyzed patients (1.1 versus 0.15 percent; odds ratio, 7.77; P significant difference in hemorrhagic complications between dialyzed ESRD and non-dialyzed patients (3.4 and 0.87 percent, respectively; odds ratio, 4.75; P

"In-hospital mortality following RFA was higher in dialyzed ESRD patients than in non-dialyzed patients," the authors write. "The indications for RFA in dialysis-dependent patients should be considered carefully."

(HealthDay)—For patients with end-stage renal disease (ESRD), receipt of hemodialysis (HD) is associated with increased mortality after radiofrequency ablation (RFA) for hepatocellular carcinoma, according to a study published online March 7 in the *Journal of Gastroenterology and Hepatology*.

Masaya Sato, from the University of Tokyo, and colleagues used a nationwide database to examine in-hospital mortality and hemorrhagic complications following RFA among patients on HD for ESRD. For each patient enrolled, up to four non-dialyzed patients were randomly selected. The authors compared in-hospital mortality and hemorrhagic complications between dialyzed and non-dialyzed patients (437 and 1,345 patients, respectively) following RFA.

The researchers found that mortality was significantly lower in those aged \geq 70 years versus [older patients](#) (P = 0.02). Dialyzed ESRD patients had significantly higher in-hospital mortality than
