PCSK9 is a co-activator of platelet function beyond its role in cholesterol homeostasis

28 August 2017

PCSK9 is a co-activator of platelet function beyond its role in cholesterol homeostasis, according to research presented at ESC Congress today. The findings suggest that PCSK9 inhibitors, a new class of cholesterol lowering treatments, may also reduce thrombosis by interfering with platelet activation.

Proprotein convertase subtilisin/kexin 9 (PCSK9) is a main player in cholesterol homeostasis by inducing degradation of the low density lipoprotein (LDL) cholesterol receptor. Emerging evidence indicates that plasma levels of PCSK9 predict recurrent cardiovascular events, for example myocardial infarction and angina, in patients with coronary artery disease, even in those with well controlled LDL cholesterol levels.

"We hypothesised that the contribution of PCSK9 to cardiovascular events might be mediated by as yet unknown cholesterol-independent pathways," said last author Dr Marina Camera, associate professor of pharmacology, University of Milan, Italy. "It has been reported that increased plasma levels of PCSK9 are associated with platelet reactivity. However, no study has so far evaluated whether or not PCSK9 directly affects the function of platelets."

"The investigators showed for the first time that:

- PCSK9 is expressed in human megakaryocytes, the cells in the bone marrow responsible for producing circulating platelets. A subset of circulating platelets contains PCSK9, suggesting that there is a finely tuned mechanism for the direct transfer of PCSK9 from megakaryocytes to a certain number of platelets.
- PCSK9 plays a role in platelet activation and aggregation.
- Platelets from patients with both type 2 diabetes mellitus and stable angina contain twice the amount of PCSK9 as patients with only one, or neither, condition.

Dr Camera said: "Our data provide novel knowledge on the mechanisms regulating platelet activation in physiological and pathological conditions. Considering the contribution of platelets to cardiovascular disease, the findings also shed light on a new mechanism that may be involved in platelet hyperreactivity in patients with stable angina and diabetes mellitus."

She continued: "Based on our data it is possible that the pharmacological inhibition of PCSK9,
besides down-regulating cholesterol levels, may have the added value of controlling the prothrombotic burden interfering with platelet activation.
