

Ultrasound helps predict the success of fistulas in individual dialysis patients

11 October 2018

Unfortunately, arteriovenous fistulas, the gold standard for accessing the bloodstream for dialysis, frequently fail to mature and cannot be used. A new study in an upcoming issue of the *Journal of the American Society of Nephrology (JASN)* suggests a strategy to identify failure earlier, permitting effective intervention.

An arteriovenous fistula (AVF), which is created by connecting a patient's own vein and artery to form a long-lasting site through which blood can be removed for treatment and returned, is the preferred way to gain access to the bloodstream for dialysis. After surgical creation of an AVF, the vessels undergo a remodeling process that is referred to as maturation. Unfortunately, 20% to 60% of AVFs fail to mature for successful dialysis use. Michelle L. Robbin, MD (University of Alabama at Birmingham) and her colleagues investigated whether [ultrasound](#) measurements after surgery could predict maturation in individual patients.

The team analyzed the relationships of various patient characteristics and ultrasound measurements with AVF maturation in newly created AVFs, measured at 1 day, 2 weeks, and 6 weeks, in 602 participants of the Hemodialysis Fistula Maturation Study.

At 6 weeks after AVF creation, ultrasound measurements of AVF blood flow, AVF diameter, and AVF depth predicted future AVF maturation with moderate accuracy. No other patient characteristic was as useful as the 3 ultrasound measurements.

"If there is a clinical concern about AVF maturation after surgery, a 6-week ultrasound can help the clinician assess the likelihood of AVF maturation," said Dr. Robbin. "If the AVF does not appear ready for [dialysis](#) access, management decisions such as the need for AVF intervention or watchful waiting for expected [maturation](#) can be aided based on

6-week ultrasound measurements of AVF depth, diameter, and blood flow."
